THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1392. Vol. XXXIV.—JANUARY 7, 1887.

FIXING AND WASHING GELATINO-BROMIDE ENLARGEMENTS.

Now that so many photographers are making their own enlargements on bromide paper, it will doubtless be to the advantage of some of our readers to give a few hints on the fixing and washing of them, so that the greatest degree of permanence may be secured with the least amount of trouble. No information on this point is required by those engaged in this work commercially, therefore it is not for them that our instructions are intended, but rather for those who only make an enlargement or two occasionally, and whose appliances are not adapted to washing prints above the ordinary dimensions.

In the present article we shall confine ourselves to the practical, and sink the theoretical part of the subject, as that has so frequently been dealt with in connection with negatives; and what applies to negatives applies equally well to paper. We shall assume that permanence of the picture is the end in view, and that towards its attainment a little extra time and trouble will not be grudged. Here are the appliances necessary:—A dish or tray to contain the fixing solution, and another for washing the prints; a rose, like that of a garden watering-pot, with very fine holes. This must be fixed in a piece of india-rubber tubing, eighteen inches or two feet long, attached to the water supply. A couple of glass plates, somewhat larger than the pictures to be treated, and a rather soft squeegee. Instead of glass, thin sheets of ebonite mounted on boards to give rigidity, may be substituted with advantage, as they are less fragile than glass.

An important point in connection with the fixing of bromide prints is pointed out by Mr. E. W. Foxlee in *THE BRITISH JOURNAL OF PHOTOGRAPHIC ALMANAC*, namely, that all trace of acid should be thoroughly eliminated before the picture is introduced into the fixing bath, otherwise there is a danger of a sulphuretting action being set up—a fact too often overlooked. Taking the picture in hand from the developing stage the first thing to be done is to free it from the acid. This may be easily and quickly accomplished by washing if a good pressure of water be available; and we prefer simple washing to treating the print with an alkali.

The print is placed face upward on a glass or ebonite plate, and a stream of water from the rose is directed upon it with all the force that can be obtained. This will quickly wash out the acid if the development has been conducted from one side only, but if the development has been effected by immersion then the back as well as the front must be similarly washed. A slip of litmus paper pressed on the surface of the print, after slight

draining, will always indicate if the acid has been removed. Experience will soon teach the operator when this has been accomplished without the necessity of testing chemically. The print is next freed from water as much as possible by draining, or, better still, by laying it on one of the glass plates and passing the squeegee lightly over the back. It is then ready for immersion in the fixing bath. This should consist of two pounds of hyposulphite of soda dissolved in a gallon of water and made slightly alkaline.

When the print is placed in the bath it should be kept constantly in motion for the first five minutes, and occasionally for the remainder of the time—not less than twenty minutes. The picture is then removed and placed face downward on one of the plates and the back squeegeed somewhat firmly to remove as much as possible of the "hypo" solution. It is then immersed in a dish of clean water and kept in motion for a few minutes. It is now removed and placed on one of the plates and the back squeegeed, and next it is removed to the other plate face upward, and a stream of water from the rose with full pressure directed upon it. Then it is transferred to the first plate again, this time with the face downwards and the back similarly treated. After this operation has been repeated on both sides, two or three times, the back is squeegeed and the print again put into clean water and allowed to soak for ten minutes. It is then removed and subjected to the syringing and squeegeeing operations as before.

By alternate soaking for ten minutes or so, and treating the picture as directed, the last trace of the hyposulphite can be more completely removed from the enlargement in an hour and a half, or two hours, than it may be with twelve hours or more of continuous soaking, even in running water, notwithstanding that the paper itself may be thick. The force of the fine jets of water from the rose dashes, as it were, the hypo out of the paper. It is needless to point out that the plates used for supporting the prints during the operations of squeegeeing and syringing should be thoroughly rinsed each time the picture is removed.

The directions here given for washing gelatino-bromide enlargements apply also to albumen prints. By treatment similar to the above, hyposulphite may be more thoroughly removed from a picture in an hour or so than it often is by simply allowing it to remain soaking in water for a whole day.

In the *ALMANAC* article referred to two fixing baths are recommended to be employed. This is highly desirable when working on a commercial scale or when a large number of prints are fixed in the same solution; but it is scarcely

necessary when only one or two have to be dealt with, provided the solution be new and there is plenty of it, and, what is of equal importance, the prints are kept constantly moving about whilst they are in the solution.

THE progress of the great Lick telescope has been a subject of great interest to the scientific of our readers ever since its inception, which the recent disaster to the extra disc which was being ground to curves suited for photographic purposes has only served to intensify. For some little time to come the fate of the perfected discs will be in suspense, as they are now about to set out on their journey across the continent of America. The lenses have been worked to the required surfaces at the works of Messrs. Alvan Clarke & Sons, in Cambridge, Mass.; and as their destination is in California it is evident they have a journey of some thousands of miles before them.

IN order that this journey may be safely performed precautions of the most careful and elaborate nature are being taken. Most photographers, probably, have, in the experience of a lifetime, wrapped up a large lens and found it a task requiring considerable care; what must be the case when the weight of the unmounted lens alone is counted by hundred-weights and the diameter is over three feet! However, the huge lenses are wrapped up, but in cloth instead of paper, and, in order to ensure freedom from scratches, the fabric has been washed many times and thoroughly beaten; it is then tightly wrapped round the discs. After the cloth comes a thick layer of paper. The box to hold the lenses is of wood, and is shaped to conform to the figure of the lenses; it is lined with felt, and the costly discs are packed tightly within. The felt is attached with glue, no nails being used anywhere near the glass.

THIS would seem to be precaution enough, but it is only the beginning; the wood box is packed into a strong steel box of cubical shape, curled horsehair being the packing material. This steel chest is again placed in another of similar material, and kept from touching it by a series of spiral springs which stud the whole inner surfaces of the last chest, both being made air-tight and waterproof. Finally, the last steel casing is packed with asbestos to make it fireproof, and the whole is slung within a wooden framework. There is yet a further provision for turning the chest round day by day on its journey, by a quarter turn at a time, the object being to prevent any molecular disarrangement and avoid the possible production of polarisation. The whole is insured for fifty-one thousand dollars.

IN making gold assays a certain amount of the material containing the precious metal is taken, and, after being melted with metallic silver, the latter is dissolved away, when the gold is left behind, and, after heating, weighed. When, however, the precious metal in the sample is excessively minute in quantity, the weighing of the small proportion left after the above operation becomes an operation requiring the greatest nicety of handling and delicacy of weighing. A very neat method of estimating these exceedingly small quantities was described in a paper by Herr Gozdorf, in a recent number of the *Chemical News*. Instead of weighing the gold, it is measured; the last drop of washing water with the contained gold particles, is guided on to a sheet of aluminium foil, and, after drying, picked up by a bead of borax in a loop of platinum wire. Upon heating before the blowpipe a perfect sphere of gold is obtained, and can be measured under the microscope with great accuracy, its weight being proved by reference to a table of constants. The writer states that the smallest bead he has measured was one a little over the two-millionths of a grain—a weight, we need scarcely say, utterly beyond the powers of the most delicate balance to estimate.

AMONG those who undertake the tinting of photographs at a cheap rate Naples yellow is a great favourite, the flesh tints can be produced so rapidly and effectively by its aid; but we would utter the strongest warning against its use. It is certain to go. We recently saw some very clever tinting in which it had been employed, and in a very short time the carnations had assumed a most ghastly hue.

OXALIC ACID has long been known as being readily decomposed by sunlight, and according to M. E. Duclaux, in the *Comptes Rendus*, a process, long sought by physicists, for measuring the chemical power of the sun's rays with accuracy may be found by utilising the above action. Certain precautions have to be taken, such as the use of flat vessels into which the same quantity of acid is always used; and taking a solution of three grammes per litre, he states the results to be very constant.

THE advantage of reducing wastes to the smallest possible bulk prior to sending them to the refiner or commencing to reduce them at home, cannot be too strongly impressed upon those who may now be collecting them. The smaller the bulk to be treated the fewer will be the crucibles, and the smaller the quantity of flux required, to say nothing of time and fuel. Many consider that if the paper be simply burnt to a cinder it is all that is necessary. But, in this cinder state, the residue occupies considerably more space than is desirable, and also is of greater weight. If, after the paper has been apparently consumed by ordinary burning, the cinders are placed in an old iron pot on the fire, they will, after a time, be converted into a pale brown or white ash which is very compact and heavy. Ashes so obtained, if the paper has been sensitised on baths of the ordinary strength, will generally contain about half their weight of pure silver.

THE chloride from the washing waters, and the sulphide from fixing baths, should always be thoroughly dried; this may easily be done in the kitchen oven. These should then be reduced to powder in a mortar, and, if time can be spared, passed through a coarse sieve. If residues were always thus treated the cost for their reduction would be far less, in most cases, than it is at present, while the returns would be eminently more satisfactory to all concerned.

SULPHURATION OF BROMIDE AND PLATINUM PRINTS.

IF ever I deliberated long and anxiously before writing an article for these pages I have done so before writing the lines that will face the readers of this JOURNAL as they peruse what I am about to write. In fact, I had some time ago written an article that would have covered a page of THE BRITISH JOURNAL OF PHOTOGRAPHY, but fearing to do any injustice to any one, or to lay myself open to the charge of perfunctory experiment, I laid aside what I had written, commenced a new series of experiments, read for perhaps the twentieth time what has of late been written on the subject with which I have to deal, and only after careful study and earnest thought I have written this, my second attempt, to throw some light on the question of the comparative durability of paper prints.

The feeling is very present to me that I may be wholly misunderstood in my intentions, that I may even be suspected or accused of either interest in one or prejudice against another process of printing—though whence my partiality could arise I cannot conceive—that some one may imagine I have a personal motive in my comparison between one process and the other. I can only say—and those who are acquainted with me will be ready, I am sure, to bear me out—that I have not the slightest partiality for any one process nor against any one person or process; that my experiments were made solely with a view to discover facts; and that my history of these experiments is given without fear or favour exactly as they occurred, and with deductions exactly as they presented themselves to my mind, whether rightly or wrongly. My trouble will be entirely lost, and I shall be very greatly disappointed, if my tests are not repeated by other persons, and if these persons, having followed me in my experiments, do not either corroborate or confute me.

Be it clearly understood that I am attacking no process; I own the "permanence" of several classes of prints on paper. A great deal has been written with a view to define "permanence," and the word "absolute" has been allowed to creep into the attempts at definition. I disown all knowledge of permanence absolute; there is no such thing in the universe. And another confusion has crept in regarding permanence, that is, a mixing up injudiciously, and a separation equally injudicious, of the image itself and the material that supports it. Both the image and its support must be permanent alike. What is

the use of a permanent image on a decaying sheet of paper? or what is the use of a permanent sheet of paper or plate of metal if it bears a fading, fleeting, decomposing image? None whatever. A print can only have value, real or nominal, if the whole print be fitted to withstand the test of time, or, more accurately, the baneful influences that must reach it in space of time. Time or age is a mere abstract idea, and can never hurt nor in any way affect anything; what we have to do with are conditions and changes and events that happen during time. The print, I say, must be impervious throughout its whole body to noxious influences; it is no gain to it or to us if one constituent fails, however well the rest of it may endure.

Now in the general acceptance of the word—certainly the word as I mean to use it—when we talk of a “print” we mean some image on paper or on some textile material. At all events, we do not mean an image on a sheet of metal or glass, if we mean such a print we say so—“glass positive,” “opal print,” or some such distinguishing name. I say, then, that a print is of no value, as far as permanence goes, if either the paper or the image is not permanent. It does very well for a convenient definition to say that an image is “permanent” if it lasts as long as its support, but in practice a print is not permanent if it is not *all* permanent. We don’t want the bones if the flesh be decayed; a skeleton is not an ornament for every lady’s drawing-room.

It is time for me to get more specially to the point of all this. Every one who reads the photographic papers is aware that not long ago grave doubts were thrown upon the lasting qualities of what we call bromide paper prints, first by the Autotype Company, who tried to draw comparisons between their own products and bromide paper in the matter of permanence by induction, and between bromide prints and albumen silver prints by analogy. They acknowledged the permanence of platinotype prints, and were soon followed by Mr. H. B. Berkeley, of the Platinotype Company, in a trilogy of letters to this JOURNAL, more remarkable for its length than for any sound arguments to be found in its text. I wish at once to get rid of the question of autotype prints, and I have great pleasure in saying that though I put them to tests of the same kind and rigour as those to which I put the other prints, the autotypes passed the ordeal, if not unblemished, at least in a way that greatly astonished and pleased me. It is true that my tests were not specially directed against the components of an autotype print, but I expected that even autotype would succumb to the tests I did apply. I repeat I was much pleased to find that one process at least withstood what was undoubtedly a severe test, and a test certain to be met with in greater or less degree in the actual life of any print—the test of sulphuration.

But it is with Mr. Berkeley I have now to deal, and if he thinks my dealing ungentle he must blame the statements he has so often rushed into, both in championship of his own process and in discredit of others.

With regard to platinotype. For years we have constantly been hearing the praises of platinotype, and nobody ever seems to have investigated the matter very particularly, and we have got to accept the permanence of platinum prints, as the Platinotype Company have always given it to us, as an axiom. It is a curious trait of human nature that if any one only goes on long enough asserting a thing, or assuming a thing as an incontestable fact, many persons will come to believe and to assume the thing asserted. I have no doubt that were I to assert with considerable violence and reiteration to the public that I was the discoverer of the law of universal attraction, I should soon be able to fill a large church with believers in my claim. History is full of examples of successful assertion. I suspect this is the case with platinum prints. I have always heard a platinotype spoken of as a thing imperishable, and “that fadeth not away,” and I never thought until lately of doubting it. I had heard of the experiments by Mr. Spiller alluded to by Mr. Berkeley in No. II. of his trilogy (page 691), but I do not now remember what these tests were; as Mr. Berkeley says some of them damaged the pulp of the paper, I gather that these ones at least were different from mine. I have heard of boiling acids being used as tests; not thinking that boiling acids are frequently met with in our average atmosphere, I did not try them; and seeing that Mr. Spiller’s tests did not affect the platinum prints, or at least the images, I conclude that Mr. Spiller omitted to try my test, which was sulphuretted hydrogen in water, a very common impurity indeed, according to Mr. Berkeley and myself, in our air.

In Mr. Berkeley’s letter No. III., as I pointed out lately, he brings in some very curious analogies between reduced images in bromide paper and such things as “silver spoons, Daguerreotypes, German gold,” &c. Analogies, when *perfect* and *complete*, are valuable arguments; when partial or one-sided they are most dangerous. On the very face of the question I maintain it is monstrous to compare a bromide print to a silver spoon, one has only to look at the two to see that comparison fails; whether they are the same in nature or not, they are visibly different in condition. But they are not even the same in composition, as surely every one knows, for each pound of silver contains eighteen pennyweights of copper. I do not say that copper is the cause of tarnishing, but I say that its presence forbids all analogy such as Mr. Berkeley would draw. All the same, if Mr. Berkeley feels inclined to be generous, and presents me with a service of plate, I am ready to overlook the copper. If he does not wish to go quite so far, I will only suggest that a certain teapot of mine is getting thin.

In the same letter No. III., “because” Nos. 4 and 5, he says, “Because a reduced silver print is not able to withstand, for many minutes even, dilute solutions of various chemicals, several of which are often found in the air we breathe in considerable quantity, . . .” and (No. 5) “because among these are sulphurisers.” This sort of assertion he carries on for several paragraphs, assuming everything that seems to suit his own argument, but without the least apparent consideration as to whether his foundation is firm or not.

It lately occurred to me that it would be well to put bromide paper to some of the tests suggested by Mr. Berkeley’s letter and my own mind, and I thought that when I was about it I might as well test a few platinotype prints along with the bromide ones. Of course, as platinotype is so well known, so universally admitted to be permanent, I thought I should have vast trouble, if I succeeded at all, in hurting a platinum print, still I resolved to try it just for fun. Mr. Berkeley’s letters pointed to sulphuration as the disease most likely to attack bromide prints (and spoons and “German gold”), so sulphur was chosen for my first tests, and in particular sulphuretted hydrogen in water. Mr. Berkeley’s concluding sentence in his correspondence runs thus:—“Let the statement go forth that some, or many, suppose that reduced silver prints will prove more lasting than the albumenised ones (this is the truth; they *do* think so).” Well, I *did* think so, and to try whether I was right or wrong, I included silver albumen prints in my experiments.

The albumen prints I used were made by myself with my usual care. The bromide prints were made by myself with probably less than my usual care, for they had been under exposed; but I found no claim on that fact. The platinotypes were, one by a well-known amateur who prints little else besides in platinum, and the other by a professional whose name is intimately connected with commercial platinum printing in this country. The bromide paper was Eastman’s “B” and “C.” My sulphuretted hydrogen was made by the action of sulphuric acid on iron sulphide, and I need not relate the incidents that attended my first manufacture of this perfume, nor tell how I stopped just in time the despatch of a mounted messenger for a plumber to see to the gas-fittings. This is matter of history, if not of hysterics!

I made a considerable quantity of H_2S and saturated water with it, used some at once, and stored away the rest for after use. My first test consisted in immersing all in one bottle, a scrap each of an albumen, a bromide, and a platinum print. In a very short time, about an hour, the albumen print was utterly and hopelessly ruined. So I do still think that, so far as sulphuration is concerned, “reduced silver prints are more lasting than albumenised ones,” and it will take a good deal to make me think otherwise. The folly of continuing to test albumen prints was so evident, that I removed the spoilt print and preserved it, and shall waste no more time with *that* subject. Mr. Berkeley may wish to continue the test, but I do not.

After about thirty-six hours I removed the platinum and bromide prints from the H_2S , but it was evening, and by gaslight I could not see the result of my test. Next morning, however, vast was my astonishment to find the platinum print completely yellow—the image side, not the back—while the bromide was, so far as I could see, as perfect as when I put it into the bottle. Of course, knowing the absolute permanence of platinotype, I put the whole thing down to a

blunder; I felt certain a bad fairy had changed the prints during the night. So, like the young woman, I "did it again." But in spite of the permanence of platinum and the well-known fugitiveness of bromide paper, and the silver spoons and the German gold, and the "infinitesimal film," and Mr. Berkeley, in spite of all these things the bromide print again, after thirty-six hours, was far superior to the platinotype. I gave up the "bad fairy" theory and put the result down to my own "blamed" ignorance and credulity. I tested my eyes for colour-blindness, but all in vain, I was forced to admit that the platinum print had "yellowed" and the bromide had not.

Then I put the scraps—fresh ones—in separate bottles of water and H_2S , and kept them seventy-two hours, and even five days, and it was always the same, the bromide came out better.

I tried a dilute solution of sulphurous acid, perhaps too dilute, for it did not affect either of the prints; had I made it stronger I dare say the platinum print would have gone wrong. I made other tests, and I found that invariably, so long as I did not destroy the gelatine, the bromide prints stood my tests satisfactorily. Chlorine, for instance, took the gelatine right off the paper, just as it did with an autotype print, and it bleached the image entirely out of a negative on a certain tissue. But sulphuration was Mr. Berkeley's cry, sulphuration was my test, sulphuration is the disease our prints have chiefly to undergo, and on the test of sulphuration the bromide prints completely vanquished the platinotype prints in my hands. I cannot well conceive how I could be mistaken in the results of so many tests (I made ten in all); but I trust some one will follow me and say whether by some extraordinary mistake I have been misled. I have gummed my scraps, with bits of the original prints, upon a piece of cardboard, and I send it to the office of this JOURNAL, where, no doubt, the "Boss of the Show" will allow any one to examine them. I ask every one to look at the prints both back and front, it will be seen that it is the front of the platinum prints that has yellowed, not the back. I do not care whether it is the back or not, my business is with prints; none the less it is the front, the image, which has gone wrong.

With a very few remarks I now leave the subject. My tests were so simple, and the results are so patent, that comments appear to be needless. It is a matter of no interest, or at least no importance, to me whether platinotype fades under sulphurating influence or not, for I cannot make a platinotype print that I care to look at; "damp," I am always told. But it was important that I should test bromide paper; I did it, and I have stated the result, to me most satisfactory. Mr. Berkeley cast doubts upon bromide paper; some of his doubts have proved baseless with regard to bromide, but well based as to platinotype prints—*comparatively*. The bromide prints suffered after a time, as will be seen on the card at the office.

I am not condemning as fugitive platinotype prints; the test I put them to was out of all reason, and I maintain that platinotype prints are what we call "permanent," but that they are injured by a solution of H_2S in water—more so than permanent bromide prints. Even albumen silver prints may, perhaps, be called "permanent," so far as sulphuration is concerned, only much less so than platinum.

But I sincerely trust that this may be a lesson to all who make as-ertion stand for argument or proof, and who are ready without proof, with nothing but a string of supposititious speculations, to condemn products other than their own.

I shall, when I have time, test prints with other impurities found in our atmosphere; not that my tests will in any way affect what I have said in the above lines, but simply for my own satisfaction.

ANDREW PRINGLE.

P.S.—Having found a bromide print with whites more pure than those of the prints I used before, I have tested it in sulphuretted hydrogen along with platinotype prints, and I send the results. This time, I think, the bromide print has suffered more deterioration than the platinum ones, still there is no doubt that the prints are all considerably damaged. With a test of such severity minute comparison of degree is a matter of little moment. Sulphuretted hydrogen injures both bromide prints and platinum prints—let us say—*considerably*.

OXYGEN MAKING.

PERHAPS a few hints upon the above subject may be of service at the present season, and may save one or the other reader from some expense and trouble. From expense, because when properly purified

the gas may just as well be made from the common and cheap chlorate, which reduces the cost materially; and from trouble, because after some experience the time of the operation may be reduced a great deal.

Retorts.—Cast-iron retorts are a great deal the most lasting, though I suppose if an explosion did occur their fracture would be more dangerous than if of wrought iron. They can be got made specially, which are better than the old mercury bottles, and more convenient; one such costs about 12s. 6d., and will last a lifetime. A friend of mine adopts another plan. He bought a Papin's digester at Benet-fink's, and got them to fit a bent gun-barrel to it. Thus he had a retort with a safety valve which is very handy to wash out, the top coming quite off, and leaving a mere open pot to clean. The tube should be amply large to avoid choking with manganese dust, and I must say I much prefer to have a safety cork somewhere. It would not be much use in case of an explosive product, but it would prevent any bursting through a choked pipe, which has happened by carelessness, though it never ought to do. No one with any experience buys a copper retort, which is only adapted to yield a few more shillings to the seller for no value whatever. The value of wrought iron depends upon the thickness, of course; it is bound to be eaten through in time by the nascent gas.

Making Gas.—There is nothing equal to a gas furnace, of almost any sort; but it is better if possible to have the whole affair arranged so high from the ground that the flame can be seen and the tap adjusted instantly without uncomfortable stooping. The proportion of material stated in the manuals is one part of powdered manganese oxide to two parts of potass chlorate, by weight; and it is best to begin with that. Buy crystals of chlorate, not powder, but crush to small size all unusually large lumps, and pick out most carefully any tiny bits of straw, or paper, or wood, which in the cheap quality are sometimes found swept up from the floor of the store bin. All this can be done in a minute or two for a lot of fourteen pounds, spreading out the whole heap on a sheet of the *Times*. If not done the large lumps are generally wasted. The proportion named will hardly ever give any startling rush of gas unless a very fierce furnace is employed. Turn up the flame well till the early bubbles have come over, and then turn down a little, but not much. In nearly all cases the gas will come over steadily. Allow about one pound chlorate to four and a half feet of gas. The best plan is to mix a lot at once—say fourteen pounds of chlorate—with the manganese, and then keep the mixture in a large tin canister with a hinged cover. It is another good plan to cut an old coffee canister to a size which just holds the "charge" necessary to fill the bag, as found by trial, and also to keep in the large canister a tin funnel with large spout, and a small scoop—I use a garden trowel, but made with a back like a scoop. Then every time you can shovel up your exact charge, and funnel it into the retort at once. It should be gently shaken evenly over the retort floor, or roughly levelled, and not left in a heap.

But, after a little practice and watching of the behaviour of the stuff, it is well gradually to reduce the proportion of manganese, first to one in three, and finally to one in four, or less. The gas will now come off much more quickly, so that a ten-foot bag ($40 \times 32 \times 24$) may be filled in fifteen minutes; but it would be by no means safe for a novice to begin with such a proportion. As soon as ever the bubbles come quickly, it is necessary to turn most gas furnaces down to about half flame; generally even so the gas soon increases, and, rather before it has got to the rush considered safe, the flame must be lowered still more, or something or other will be blown off by mere pressure. When in full swing the evolution of gas will go on with little check long after the flame is quite out, and it is this behaviour which the beginner has to learn before he tries to hurry matters. On the other hand, at first he will turn down too much sometimes in over caution, and the gas will stop, when it takes a good while to start it again. Getting a bag filled quickly really depends upon avoiding both mistakes, and by timely adjustment keeping the process going at a fairly rapid rate from first to last. This rate is much faster than a novice would suppose at first, but it would not be safe to work up to it otherwise than gradually.

Such a rate of work will always deposit some manganese dust in the tube between the retort and first wash bottle, and it is very important that this—both the retort pipe and the rubber tube—be

perfectly cleared before the next operation. To avoid this, some use the manganese finely granulated instead of powdered. I have had no experience of it in this state. The well-known caution about any possible contamination with carbon need not be enlarged upon here; but one cannot be too particular in insisting, under all circumstances, upon the rubber tube being taken off the retort delivery tube *before* the retort is removed from the flame. If this is neglected, and the retort should become perceptibly cooled while still connected with a wash bottle, there will be a partial vacuum, water would be sucked back into a highly-heated iron vessel, and the result would be a *steam* explosion. It will be seen, therefore, that under given circumstances there might occur either an *over-pressure* explosion, a *carbon* explosion, or a *steam* explosion. To see these things is to disarm them. The arrangements immediately described offer an effectual safety valve against mere over-pressure. But the pipe, from retort right down into the wash bottle, should on no account be less than half an inch clear bore, rather more preferable.

Washing the Gas.—A large proportion of the gas made is never properly purified, and the consequence is a rapid destruction of bags and taps by no means necessary. If a tap shows any perceptible corrosion—much less green rust about it—the gas is used when foul with chlorine. The same if the gas has *any* pungent odour, from which even fairly pure oxygen is perfectly free. There is much popular error on this point. 1. Water alone will not purify gas;

2. One bottle will not do it unless nearly a yard deep. As to the medium, many use either potassium carbonate or sodium carbonate (common washing soda), and either answer fairly well, but will not purify a very foul sample. I prefer to use *caustic* soda or potash, which will entirely remove the chlorine. Caustic soda is usually sold in sticks about five inches long: use a couple of sticks to a gallon jar. The same solution of this may be used three or four times over, which saves trouble. The oxygen should be passed *twice* through this, and may then be regarded as pure.

Common washing bottles with their screw caps are very troublesome. For years I used vulcanised indiarubber Woolf tops, with rubber nozzles through which the pipes were passed, stretched over the necks of the bottles. These are much better. But for a still better arrangement, combining the maximum of efficiency with the very minimum of trouble, I am recently indebted to Mr. Charles Darker, an ingenious artist—

for he is truly such in all optical matters—to whom we are all indebted for more than many are aware. His cap for washing bottles is shown in the figure. A is the delivery pipe of brass going down into the solution. This passes through and is soldered into the cap B, into the side of which is soldered the exit tube C. And over the cap B is stretched about two inches of thick indiarubber tube D. The whole is made so that the lower end of this stretches over the mouth of the usual size wine bottle. On a journey, therefore, these can be used, and no bottles need be taken, nothing but the caps and tubes. And whenever the rubber D loses its stretch, there is only this piece to renew; the rest is as good as ever. It is put on and removed in an instant, and the whole arrangement speaks for itself. Over-pressure will force it off the bottle, and to this danger it therefore acts as a safety valve.

One of your contributors, I think it was Mr. Scott, was, however, quite right last year as to the desirability of large wash bottles, and for home use it is better to use gallon size, which is easily got of the same sized necks. Use two of these, nearly full, and the gas will be pure. It will, however, be also moist, which is bad, too. To avoid this, use a *third* cap on a *narrow* bottle, empty or dry, such as a thin champagne or hock bottle, or a piece of large glass tube. The moisture will collect in this and only dry gas go into the bag. The tubes should go nearly to the bottom of the wash bottles, and the

side holes not be bored very high up, or the gas will not have to rise through sufficient liquid.

All three bottles can easily be kept arranged on a little shelf if desired, but it is better to take off the caps after use that the rubber part may not lose its spring.

Of course, when the bag is full and the tap turned off, the tubing will also be detached instantly. The next step is to detach the tube from retort, as already insisted upon. Then turn the nozzle up the chimney till cooled down. It is best to wash out the same day, as the chloride residuum is rather destructive. Some remove it dry, breaking it up with a pointed rod, but it is much more trouble, and I think wears the retort more. When washed out, care must be taken to *dry* it out thoroughly, and do not forget to clear the delivery pipe and rubber tube of manganese dust, as already hinted.

The difference in wear of bags between gas thus properly purified and gas either delivered direct, or merely washed with water—it cannot be called purifying—is simply amazing.

LEWIS WRIGHT.

ON THINGS IN GENERAL.

"CAN photography lie?" What a terrible implied imputation! And I am indeed afraid that photography cannot be at all likened to Cæsar's wife, for it is not above suspicion. When one finds a well-known photographer putting the above question (see report of the transactions of the London and Provincial Photographic Association) it is as good (or as bad) as a verdict of Guilty, at the outset. We are brought back to the old reply, "Truth is hid in a well," and it is the real truth that such is the case in regard to matters photographic. I find it hard to believe Mr. Bridge's friend who managed to secure £150 for services rendered to the two opponents in the case of a contested railway matter. But if this question itself be so horrifying, what will the British Public, or that large section of it that reads THE BRITISH JOURNAL OF PHOTOGRAPHY, think of the reply subsequently given at the Camera Club by Mr. J. Traill Taylor, "There was no room for doubting that *photographers*, as such, could and did?" Now, really, Mr. Taylor—I won't say Mr. Editor, for he spoke as a photographer, and not an editor—what am I to understand? Do you mean to accuse me of mendacity because I happen to possess a camera and a lens? But no, that is impossible. I call to mind an old speech of the sort I heard a great many years ago. A printer had outraged the patience of one of his customers for so long a time that at last he got angry. "Well, I will give you my word the things shall be printed to-morrow," said the printer. "Is it the word of a printer or the word of a gentleman you mean?" retorted the injured one. I will imagine Mr. Taylor to have spoken in a Pickwickian sense.

I was much amused at the remainder of the discussion that occurred the same evening in relation to the difficulty of pleasing sitters. I do not think any one not used to the work can have any idea of the great difficulties experienced by those who have to paint by the sun's light. It is not necessary to believe that Mr. Henderson exaggerated the least when he speaks of one sitter—a gentleman—having employed himself for two or three hours before a looking-glass in arranging his position. I have myself seen an instance of a sitter of this class, who had taken about half an hour to pose, call out to the operator, just as the latter was going to uncup, "Now, how would this do?" throwing himself, at the word, into an entirely different attitude, and requiring all the arranging to be gone through again.

The great question of the hour seems to be orthochromatic or non-orthochromatic plates, and, clinging to its fringes is another, "lawsuit or no lawsuit?" There would be a great advantage to the community if only the question could be fought out for them; the combatants would have to pay all costs, and if, as is quite possible, the so-called "infringers of the patents" gained the day, then the process would be thrown open to the public at large. A patent suit, at the best, is nothing but weariness and vexation of spirit, and when it is mainly supported by, or combatted upon, scientific, and especially chemical, evidence, the way the verdict will be brought in is a pure question of chance. This kind of evidence has been described by a well-known literary and scientific man as follows:—"Positive, men-

dacity; comparative, outrageous lying; superlative, scientific evidence." And I think he is not far wrong in his conclusions.

What is all the stir one sees happening at the meeting of an amateur society in a city well known for its connection with photography? A gentleman seems to have made a business of his amateur work some years ago, but the club or society condoned his offence; now they have reopened the question, and, by a resolution to the effect that "Any person now or at any time a member of this Association who shall practise photography professionally, sell, or publicly expose for sale photographs of his own production, shall thereupon cease to be an ordinary member of the Association," have, apparently, ostracised him. That is a resolution which with a prospective action only might be with advantage adopted by all amateur societies. Their ranks would be well thinned, for it is my belief that there are very few amateurs who do not sell their productions—professedly at a price, "just enough to cover the cost, you know," the cost, I suppose, of all their experiments, hire of instrument, and all etceteras, so as to make them free of all expense in the fixing of their hobby. I wish to observe, though, that in the resolution above quoted the word "shall" cannot grammatically (though I suppose the intention of the framers is not carried out in the words) be considered to apply to the past.

I note that at the last London and Provincial Photographic Association meeting some discussion upon platinotype printing took place, in which the speakers alluded to the difficulty of introducing modifications in the printing, as is commonly done with silver prints. Now there is no doubt that there is some increased care and judgment needed in the operation—it is scarcely one that can be deputed to "the boys;" but there is a fairly visible image in an undeveloped platinum print, and, personally, I may say I have found it a comparatively easy matter to introduce clouds into platinum prints. It is, however, requisite to take care that the time taken over the work be not prolonged too much, or the character of the results will suffer; for a very slight absorption of moisture by the paper renders it impossible to obtain purity of whites. By-the-by, I should like to know whether the pages of this JOURNAL are going to be permanently increased for the next year or two, to allow of more lengthened correspondence upon the "permanent" question? Can any one doubt that the readers will be pleased if such be the case, all the letters, so far, having been such nice, light, instructive reading? (I hope no one will think that by light I mean frivolous; for all frivolling is discountenanced from the editorial chair, I know.)

The articles upon retouching by Mr. Barrett that have been appearing for some months past in these columns, are written by a man who is at once artistic in feeling and capable of expressing himself in suitable words; but I should like to say of them that—assuming, as I do, from its last paragraph, that the paper printed at the end of December was the last of the series—there is a glaring deficiency in them. To the best of my recollection there is not one single word about the manner of using his tools. As to the calibre of the work to be done there is plenty of instruction, but as to the mystery of spot, dot, stipple, lines curved and straight, hatching or cross-hatching, not one word. Now it may be that Mr. Barrett intends to introduce some such instructions at the end of his work—that I cannot say, but one might fairly expect the series of articles to have begun with something of the sort.

At the close of exhibitions, photographic or otherwise, there are always, and as a matter of course, letters denunciatory of management, selection, and all other authorities, published in all the periodicals that will admit the lucubrations of the disappointed ones; but this time the cry has swelled to such a chorus of unbroken complaint as to breakages and damages that there is clearly some one at fault. A scapegoat will have to be found, for it is evident the gilt has all been rubbed off the frames. Some gentlemen have even not had all their pictures hung—would it be believed! May I make a suggestion to the authorities to have a supplementary exhibition of the works of the forsaken ones? I think one such exhibition should entirely for the future put an end to such wailing, for as the hangers were so regardless of the best interests of some of the senders as to hang a few of the atrocities, it is easy to imagine the character of what remained in the cellars, rotting I was about to say, but I am afraid there is no such kind fate in store.

In the report of the Manchester Amateur Photographic Society's

meeting last month, I read that "a novelty in the lantern display was the use by Mr. Jones of gas compressed into steel bottles instead of gas bags." Now I happen to know, as also do many of my readers, that there are some exceedingly wide-awake men in that Society, and I don't think they would look upon the compressed gas as a novelty.

FREE LANCE.

PHOTO-MICROGRAPHY.

[Abstract of Paper read before the Photographic Society of Philadelphia.]

ANY stand, monocular or binocular, the body of which can be inclined to a horizontal position, may be employed. In using a binocular stand it is merely necessary to withdraw the prism sufficiently to allow all the light to pass up the straight tube, and thus convert the instrument into a monocular. The eye-piece may be removed or not as the operator desires, the former plan being the one generally adopted and producing, so far as my own experience goes, the better results. If the eye-piece is not used, the tube must be lined with some non-reflecting material, as before stated. A mechanical stage is a great convenience and time saver in centering an object upon the ground-glass, but is by no means a necessity; it should, however, revolve in the optical axis of the instrument if possible. A double or triple nose-piece carrying as many object glasses of different foci is also very desirable, especially when high powers are to be used, as an object can be quickly brought into its proper position in the field of view under a low power, when by revolving the nose-piece a higher one takes its place, and if the two are properly centred, the object will be found to occupy the same position in the new field of view.

The placing of the object on the stage of the microscope, and arranging it in such a position as to cast its illuminated image upon the centre of the ground-glass focussing screen, are all to be done with camera closed up short, in which position the eye can readily see the image, whilst the hands reach the milled heads controlling the stage and focussing adjustments. But when the bellows are extended a foot or more this becomes impossible, and resort to some other method of varying the focus is necessary. The plan I adopted at first, and have ever since followed, was the old but effective one of a strong, fine cord placed in a groove turned in the periphery of the milled head controlling the fine adjustment of the microscope, and passing through hook eyes on either side of the camera to its rear, where it is held taut by a couple of small leaden weights. A very slight pull on either of these serves to change the focus in the most delicate manner, and this can be done whilst the eye is fixed upon the image on the ground-glass.

I have used the term *ground-glass* in connection with the fine focussing adjustment, but merely as a figure of speech. In reality ground-glass cannot be used for this purpose at all, as the very finest that could possibly be made is entirely too coarse to define sharply any delicate microscopic object. Its usefulness is confined to securing a full and even illumination of the field, and the arranging of the object in its proper position therein. These two essentials arrived at we must abandon the ground surface in favour of something better adapted to giving a sharply defined image of the magnified object. Many plans for effecting this have been published, but I shall at present notice only the two which I have used most successfully for some years. The first, which is useful for hurried work, consists in attaching to the centre of the ground surface of the focussing screen, by means of Canada balsam, a disc of thin microscopic covering glass about an inch in diameter. The balsam fills up the minute inequalities in the surface of the glass made by the grinding process, and renders the circle perfectly transparent. Now, if a Ramsden positive eye-piece, or any ordinary focussing glass adjusted to the thickness of the screen, be applied to the outer side thereof, the illuminated image will be seen clearly defined in this transparent circle with the most beautiful distinctness, when the proper focus is made with the adjusting cord.

This method, however, only allows that portion of the object which is in the centre of the field to be seen and focussed upon, whereas it is frequently desirable to go all over the same to arrive at the best average adjustment. For this purpose I use the following plan, which is so perfect in its results that I can conceive of nothing better: A sensitised gelatine plate, evenly coated, is exposed to a flash of light, and placed in the developing bath a short time, until it becomes somewhat discoloured, or clouded over, but not long enough for it to acquire any destiny. It is then washed and fixed as usual; after fixing and a prolonged washing, it is bleached with bichloride of mercury as for intensification, and again washed and dried, when it will be found to possess the finest surface for delicate focussing imagin-

able. And now comes in the use for the single plate holder, to which I have before referred.

Slide and back both being removed, the holder is reduced to a mere framework, which is placed in position on the camera, the ground-glass screen having been lowered out of the way. The bleached gelatine plate is now placed in the holder (film side toward the image), where it occupies exactly the place that will subsequently be filled by the sensitised plate. The positive eye-piece, or focussing glass, being now placed against the outer surface of the plate, and the eye applied thereto, perfect definition may be effected by means of the focussing cords, the proper position of the image upon the plate having been previously secured through the medium of the ground-glass.

A few words as to the objectives may not be amiss. For powers including one-quarter of an inch and higher, no special corrections are necessary. I have had most excellent results with the higher powers of very many of the best makers, both American and foreign, and even the cheap French triplet quarters have produced very good work without further correction. But for all lower powers a special correction, to render the actinic and visual rays coincident, becomes necessary for perfect work.

The proper illumination of the object is of the first importance, since, if we fail in this, all our other efforts are of but little account. Various sources of light are at our command. The direct rays of the sun, diffused daylight, the electric light in various forms, magnesium ribbon, or the oxyhydrogen jet, can all be used most successfully by those able to command time and apparatus. But my remarks at this time being intended mainly for the benefit of those who have only their evenings at their disposal, I shall confine myself solely to the consideration of that illuminator procurable by every one—a good lamp burning coal oil. Any form capable of being placed at a proper height to suit the stage of the microscope may be used, though some are undoubtedly better than others. The one I have adopted, and find eminently useful, consists of a broad, flat reservoir, with large capacity, carried at any desired height upon an ordinary retort stand, and using a duplex burner, with the flames placed at an angle to the plane of the stage, in order to avoid the dark spot in centre of field which always results if the flames present their edges to the object slide. The stage of the microscope should be provided with a set of diaphragms of various sizes, the arranging of the object being done with a large opening, whilst the exposure is made with the smallest which will properly and evenly illuminate the field of view. If desired, a condenser can be used to concentrate the light upon the object; but for a long time I have entirely discarded its use with all powers lower than one-fifth of an inch, using the direct rays proceeding from the lamp alone. This gives a more evenly lighted field, and although the length of exposure is somewhat increased, the resulting negative is better in every way than one made in a shorter time by a strongly concentrated light.

The difference in fact is very marked, and I would urge upon every one using lamplight to dispense with all condensers with moderate and low powers. With high powers, however, a condenser becomes necessary, and an achromatic combination of wide aperture, or one of the Abbé form, may be used with the best results. Some operators use blue or ground-glass for toning and diffusing the light. In short, the subject of illumination is an exhaustless one, and I shall not attempt to pursue it further at present. Neither can I give any certain rules as to time of exposures. The length of these vary greatly with the nature and structure of the subject, so that every one must learn to determine this for himself, as in ordinary photographic work. Using a given objective, and with the same plates and illumination, I have had exposures vary from ten seconds to five minutes, regulated entirely by the difference in the colour and structure of the subject to be photographed.

For all delicate structures, especially finely marked diatoms, I find it much better to develop for detail only, resorting to after intensification to obtain necessary density. By this means none of the finer lines or markings are obscured by too heavy a deposit, whilst the negative is quite as permanent as those not intensified, if it be first bleached in a solution of bichloride of mercury, and blackened by immersion in cyanide of silver, or a ten per cent. solution of sulphite of soda. Ferrous oxalate or pyro development may be used with equally good results. At first I favoured the former, but of late years have, in common with most others, grown more and more accustomed to pyro, which, with carbonate of soda, has given me results uniform in their success, and of a quality leaving little or nothing to be desired. I use no restrainer excepting the sulphite of soda in solution with the pyro, the resulting negatives being uniformly of a pleasant grey tone, entirely free from the yellow stains so often associated with the use of pyrogallie acid.

For making prints, bromide paper is especially recommended. It can be used in the camera for enlarging or reducing, or be printed by contact, by day or lamp light, as desired. It renders all delicate details better than albumen, the finished prints need not be mounted, for book illustrations they are perfect, whilst, finally, I think there can be no reasonable doubt of their absolute permanence. If a glossy surface is desired, it may be obtained by squeegeeing the print upon a sheet of polished hard rubber, from which it will peel off with a glazed surface when dry, as seen in the specimens now submitted.

Since the making of transparencies from microscopic negatives differs in no wise from those of other subjects, I shall not detain you in alluding to them further than to repeat that reduction in the camera gives more satisfactory results than contact printing, and that this is the plan I almost invariably pursue, even if the negative be upon a quarter-sized plate.

It adds very greatly to the scientific value of a photograph of any microscopic object, if the exact magnification be measured and stated thereon. To do this separately with each exposure would entail an expenditure of time and labour that few would care to assume, but if each objective be carefully measured with the camera closed, and also opened to the full extent of the bellows, and notes thereof preserved, it will be an easy matter to calculate the exact amplification used with each exposure. This measurement is very easily made. A stage micrometer ruled in one-hundredths and one-thousandths of an inch is placed upon the stage of the microscope, and the image thereof focussed upon the ground-glass, where the value of each division is readily determined. I would advise every one turning his attention to this branch of photography to make such a series of measurements at the outset.

As previously stated, any microscope with a joint for inclination of the body to a horizontal position may be employed in photography, but those having a short tube of large diameter will do better work than those with long ones. It is highly desirable that the rays of light, after passing through the objective, should be allowed to diverge as speedily as possible. Where they are confined to the limits of a long tube of small diameter, it will be found that only a small circle of light will be thrown on the ground-glass when the camera is closed up short, and that it must be lengthened to a considerable extent before the entire plate is illuminated. In order to overcome this objection, I devised, some years since, a stand from which the compound body may be entirely removed, and replaced by a cone-shaped tube which flares away from the back of the object glass, allowing the image-bearing rays to diverge at once after leaving the lens.

W. H. WALMSLEY.

PHOTOGRAPHING WITH PHOSPHORESCENT SUBSTANCES.

At a meeting of the Franklin Institute, Mr. Frederick Ives read a preliminary communication on this subject, giving the result of some investigations which he had undertaken at the suggestion of Dr. Wahl.

After making a photograph of a street scene by exposing in the camera for thirty seconds a tablet coated with Balmain paint, and then placing it in contact with a photographic sensitive plate for about the same length of time, Mr. Ives made exposures on the lime-light spectrum, to determine to what kind of light the tablet was sensitive. He found that phosphorescence was produced only by exposure to the violet rays, and that the light given out by the excited tablet was chiefly the indigo blue, to which photographic sensitive plates are more sensitive than to any other colour. But he also observed that a tablet exposed to sunlight, and then given a rest of several hours in total darkness, in a cool place, became quite sensitive to the dark heat rays at the opposite end of the spectrum, which caused a temporary exaltation and corresponding rapid exhaustion of the feeble phosphorescence remaining in the tablet. He succeeded in obtaining strong photographic negatives showing this action, and concluded that by this means it would be possible to obtain camera photographs of perfectly dark objects which radiated or reflected sufficient heat, provided that the lenses used were capable of freely transmitting such dark heat rays.

M. Ch. Zenger, in a recent communication to the French Academy of Sciences, asserted that he had obtained a photograph of towers and other objects at midnight on a dark night by the aid of a phosphorescent tablet, and attributed the result to the action of dark "actinic" radiations, which he supposed that the objects gave out at night. Mr. Ives pointed out that, as the tablet proved to be insensitive to such rays, Zenger's explanation was certainly incorrect. Mr. Ives's investigation had proved that bodies intensely heated by exposure to

the sun during a hot summer day might, under certain conditions, be photographed at night by the action of heat which they radiated; but the method did not seem sensitive enough to give such results with glass lenses, and he thinks Zenger's photograph may have been due to unsuspected feeble phosphorescence remaining from a previous exposure in daylight, several hours or even a day or two before.

Mr. Ives offered explanations of other phenomena observed by M. Zenger, and concluded by claiming to be the first to discover that photographs of dark objects may be made in the camera by the action of heat which they radiate or reflect.

ON CAMERAS AND FIELD APPARATUS.

[Abstract of Paper read before the Camera Club.]

THE type of the new form is the camera, now well known, brought out about two years ago by McKellen. I think I shall not be far wrong if I say that this type of camera claims to obtain rigidity, not by additional bulk or weight of material, but by an improved disposition of the parts on mechanical principles.

The question arises how far the advantages of the new form are real, and whether, if real, they are obtained by the sacrifice of the good points to be found in the older cameras? This involves the determination of the points necessary to a perfect or ideal camera, on which I will venture to give you my views to-night, with the object, I would add, of eliciting, rather than imparting, information.

1. The first essential of a camera, I take it, is that it should be as light as is compatible with rigidity; not, as some makers seem inclined to read it, as rigid as is compatible with lightness. As far as I have tested them, the new form, with folding fronts and backs, in "triangular positions" (to adopt an inaccurate but sufficiently understood phrase), are as rigid as the old, when not too fully racked out. When, however, they are used at their greatest extension they seem to me hardly as rigid as the older forms.

2. Both vertical and side swings are necessary in a perfect camera. The latter is not found in some of the new types, the makers conceiving that they get the same result by swinging the front, which is a delusion. In most of the new cameras the vertical swing starts from the hinge of the back, and not, as in the old forms, from the central line of the ground-glass. Every time the swing back is used on a new type of camera, the focus has to be readjusted. This is a distinct disadvantage of the new forms, as at present made. It is only fair to say, however, that the defect is not inherent, and might be remedied with ease. In fact, I have seen some new cameras, to which the old form of swing was adapted in addition to the new.

3. It is important that the lens should be capable of motion, both lateral and vertical. A much greater lateral motion than is usually given, even in the old camera, is necessary if two pictures are to be taken on one plate. In the new types the matter of lateral motion does not seem to have been sufficiently considered, though the vertical rise and fall is all that could be desired.

4. One requisite—not yet, I believe, supplied by any camera—is some means of taking smaller sizes of pictures without recourse to the clumsy expedient of carriers. It might be easily done by an extension of the principle of the sliding board commonly used for stereoscopic pictures. This board would carry grooves for the smaller-sized double backs, and would block out all the back, except the opening in the centre to receive the small slides. By this means the necessity for a second focussing screen is obviated.

5. A fifth point of great importance is that there should be some means of arranging the camera, so as to give both vertical and horizontal pictures. The old way of turning the camera over and re-screwing it was about as bad a way as was ever devised. Independently of the trouble involved, the camera was never sufficiently rigid in the second position—it was balanced, so to speak, on a knife's edge. The new way of making the camera square with a reversing back is convenient, but adds bulk and weight.

6. Most new cameras are now made with a great extension of focus. I am not of opinion that this is very necessary for field work. The use of a long-focus extension is mainly for copying and for portraiture. Both are operations that can be done at home by means of one of the "extension fronts" that are supplied by some makers, or by studio and copying cameras, if the amateur can afford to possess them.

7. An improved method of focussing is very desirable. The focussing cloth is an abomination, only tolerated because it covers the defects of our double back. Combined with the new arrangement should be a means of seeing the picture in its right position—that is, not upside down. A mirror hinged to a light frame capable of attachment to the back of the camera is what I would suggest.

When the picture has been satisfactorily composed, the apparatus would be removed, and the fine focussing performed by the ordinary focussing magnifier applied to the ground-glass.

8. In the ground-glass itself some improvement is desirable. The coarseness of the grain is very objectionable when magnified for focussing purposes. This is a great drawback where small pictures are taken for enlargements. Plain glass gives the most satisfactory image for the magnifier, but is not equally advantageous where the picture, as a whole, has to be judged of. Abney's "white wax, dissolved in ether and flowed over a plate," may make an excellent surface for studio work, but is hardly suited for the field.

9. A dark slide that will open inside the camera is a *desideratum*. Many such have been from time to time produced, but they all have the disadvantage of precluding the use of short-focus lenses. The double back supplied by Brandel, with his so-called "photo-revolver," seems to me excellent in conception, and I shall be glad to see makers adapting the principle to their cameras.

So much for the camera. As to stands, no great improvements have been made of late, if we except the turntable, which is, to my mind, a distinct advantage. The majority of stands take too long to set up.

A lens shade of some kind is, I think, a *sine qua non* for field work. I know of nothing simpler than to use the focussing cloth, stiffened at the end by a piece of cane let into a seam to cover the lens instead of the ordinary cap, and be lifted to form a lens screen during exposure.

H. H. O'FARRELL.

THE PROGRESS AND DEVELOPMENT OF ORTHOCHROMATIC PHOTOGRAPHY.

ONE of the greatest advantages in depicting objects by photographic methods is the truthfulness and accuracy with which they are rendered upon glass, paper, or other carriers of sensitive films. The remotest fibre and infinite structure of microscopic animals is reproduced by the camera with such exact sharpness, that student or investigator is enabled to project them in enormously enlarged proportions with equal exactitude. Architectural drawings and other designs are reproduced in correct angles, perfect copies of the original, and the human face is found upon the photographic plate not only as a true image but with all imperfections nature has given it. Every line, every elevation, is there equally sharp with hair or beard, and all is reproduced without mercy to the original. Considering these and similar points, photographs are indeed correct representations. In one respect, however, photographic pictures are almost devoid of veracity, that is, in the reproduction of colour values. When we examine photographic pictures, it is seen how very little truth there is actually in them in regard to colour. Scarlet and yellow, which appear bright to the eye, are represented in a sombre, dark tone, and blue or violet, no matter how dark in the original, are, in the picture, quite light, at times even white.

Light, divided into its spectrum rays and then projected upon a sensitive photographic film, will not act in proportion to its colour brightness, or as the eye is impressed, but in proportion to a certain force or power called actinism. The chief action will take place in the spectrum region from violet to blue; and those parts containing the bright colours, green, yellow, orange, and red, will scarcely be acted upon, showing that the visible effect on the eye is not at all a representation of the chemical or actinic force. The term photography is, therefore, not absolutely correct, for light in its entirety does not right, but a portion of it only, the chemically active or actinic rays.

With the rapid strides which photography has made in late years, a mode of operating has been discovered, which has not emanated from the brains of one single man, but which to accomplish all enthusiastic researchers in photo-chemistry and spectrum analysis have contributed. We have seen how the luminous light rays act upon photographic plates but to a limited degree, or not at all, and how others, appearing much darker, show excessive force. Pigment colours in action correspond very nearly to those of the spectrum, although the latter are preferable for experiments, or the determination of the action of a certain ray. The more refrangible rays, violet and blue, are actinic, that is, photographically active, while the luminous rays, red, yellow, &c., have but little photographic action. The end in view was to use these latter rays in photographing as well as the former.

The elder Dr. Draper experimented on the action of spectrum colours as early as 1850, and came to the conclusion that only those rays become active upon sensitive bodies which are absorbed by them. Extensive studies in spectrum analysis led to various experiments, and the propounding of various doctrines. Ducos du Hauron and Cros

interposed coloured glass screens between objective and sensitive plate to intercept certain rays, and to control or to depress their force. A yellow screen depresses the action of blue, and red that of green.

The first yellow coloured plates came from England, but they had no practical value, although they gave an impetus to more direct investigations and experiments on the absorptive power of coloured films. If plates are coloured with a yellow or orange dye, blue and violet rays will be intercepted, and the force of their action reduced. Green will act similarly on red rays, and red on green. The first attempts of scientific value were based directly upon the results of spectroscopic researches, and two colours, coralline and aurine, were employed to counteract the violent force of violet and blue. Not less objectionable were those of yellow and red.

At the occasion of the sun's eclipse in 1873, a meeting occurred between a German investigator and Captain Waterhouse, of Calcutta, who was then induced to resume and continue his experiments, in consequence of which a newly discovered dye, the eosine, was proposed for colouring plates.

In the meantime American scientists had not been idle; the eminent Carey Lea made the subject a part of his studies; Frederick C. Ives employing the green chlorophyl for the depression of red, and Edward Bierstadt, in many directions experimented in orthochromacy.

In 1881, Clayton and Atont Tailfer, Frenchmen, patented and published a method (isochromatic they called it), with which the desired effects could be obtained to a very high degree. They added eosine to the emulsion of bromide of silver and gelatine, and gave a still greater susceptibility by adding small quantities of ammonia. The process was enthusiastically received, for with these eosine plates and the use of a yellow screen blue and yellow were reproduced nearly correct, although the other rays did not respond so well. Highly interesting experiments with important results then followed rapidly, and some of the most renowned scientists resumed photo-spectrographic studies, and directed their attention to the action of the less refrangible rays, yellow, orange, and red.

The important labours of Victor Schumann, Dr. Eder, Charles Scolik, and Captain Abney led to the most marvellous results in orthochromatic photography, and among Americans we find Ives and Bierstadt again at the front, the former directing his attention to the action of chlorophyl in combination with eosine and other dyes.

Now we are able to copy the sun spectrum and nearly all pigment colours upon the sensitive plate. Of more than two hundred dyes experimented with, only a few have been retained for their efficient actions; eosines in various shades, blue and red chinoline, some of the anilines, and of vegetable substances, chlorophyl and turmeric. The mode of applying these colours to the sensitised film has been greatly simplified, and the photographer is now enabled to prepare a colour-sensitive plate for immediate use.

Ordinary gelatine dry plates, preferably those which carry in the emulsion but a very small amount of iodide of silver, are subjected to an extremely diluted bath of ammonia to give them susceptibility for the dye, and are afterwards subjected to the action of erythrosine—a dye belonging to the eosine series—and also in very diluted solution. The preparation of a plate requires not more than four or five minutes, and no other precautions are required than to work in nearly total darkness and to subject the plate to the colouring bath but for a limited time. Too much colour will reduce the general sensitiveness. In contradiction to the term isochromatic, the method is now called orthochromatic, meaning to reproduce colours correctly as to their brightness, while isochromatic implies uniformity of colours. A better and more descriptive word would probably be the plain English colour-sensitive.

The practical value which orthochromacy offers to scientific pursuits cannot be over-estimated, when we consider that objects formerly quite inaccessible to the power of a sensitive plate can be successfully photographed now. Prof. Pickering, of Boston, and the Brothers Henry, of Paris, have obtained pictures of the optically invisible nebulae of the Pleiades, and Prof. Huggins has made a photograph of the corona of the sun when not eclipsed, while Spitaler, of Vienna, has made pictures of the moon with a telescope corrected for optical rays only. Microscopic objects are in frequent cases copied with the aid of chinolines and erythrosine, and spectrum analysis finds in colour-sensitive plates an indispensable aid. The professional photographer who reproduces with them oil paintings and other works of art, is enabled to make copies of fabrics or embroideries, no matter how greatly non-actinic colours may be prevailing. The retoucher's work in portraiture will, in a measure, be dispensed with, for light yellow or brown freckles do not show on an orthochromatic negative, and light auburn or gold coloured hair will photograph light, not black as heretofore.

With the extreme sensitiveness of erythrosine plates for yellow, orange, and red rays, artificial light has been pressed into the service of the photographer. Incandescent electric light, the gas flame, and even the ordinary petroleum lamp, give good light to photograph on colour-sensitive plates.

While great credit is due to German scientists for having done the pioneering in spectrum photography and orthochromacy, Americans have not remained inactive, and they have contributed much to make the methods of photographing upon colour-sensitive plates practical for the daily use of professional and amateur photographers.

CHARLES EHLMANN.

ACCESSORIES OF THE LANTERN.

CHAPTER I.—GAS BAGS.

EVERY lantern operator knows what an important part of his outfit the gas bags are. Supposing he is using the mixed gas jets he requires two bags, and the cost of these accessories will be nearly as much as the price of the biennial, especially if the latter is a cheaply made instrument. The gas bags are not only expensive as regards their first cost, but they also form the largest item in the cost of maintenance. The lantern with its fittings and the slides may keep in good order during years of constant use, and cost little or nothing in repairs, but the gas bags, more especially those used for oxygen, deteriorate so rapidly that the work of a single winter season often wears them out completely. The life of a gas bag in constant use being so short, any means by which it can be lengthened will naturally be of interest to those whose purses are affected by the matter.

The material of which gas bags are made is rendered air-proof by one or two films of indiarubber, by which the cloth or twill, which is used in two or three thicknesses, is cemented together. Upon the substance of this indiarubber depends the longevity of the gas bag. In the best bags the rubber is over a sixteenth of an inch thick, and of course resists the corrosive action of the gases for a much longer time than cheaper bags made air-tight by a mere skin of rubber.

When a gas bag begins to leak it is not so much the cloth which is defective as the layer of rubber attached to it, which has become rotten. Hence it is real economy to purchase a first-class gas bag in preference to a cheaper one of the same size; the extra cost will be amply compensated by increased durability.

All new bags should be thoroughly tested, to ascertain if there is any leakage. This may be done by filling the gas bag with air or coal gas, and placing it between the pressure boards with a half-hundredweight thereon. If the top board only sinks one or two inches during a period of twelve hours the bag may be considered sound; if the bag is only half full at the end of that time it is still serviceable, as the leakage during the two hours of an exhibition would not be very serious, still, such a loss should by no means be tolerated in a new bag. Sometimes the leakage is caused by the plug of the tap not being screwed up tight enough, or from not being properly greased with tallow. If the leakage is not connected with the tap the bag should be returned to the vendor, with a request for a sound bag to be given in exchange.

As gas bags are used for both oxygen and coal gas, and as it is extremely dangerous for these gases to be mixed together in one bag, it is necessary to use each bag constantly for the same gas. As a general rule, a bag used for oxygen should never on any account be filled with coal gas and *vice versa*; the bag which is used for coal gas should be a complete stranger to oxygen. The non-observance of this rule is the cause of perhaps one-half of the explosions that occur in connection with lantern work. It is a good plan to paint in large white letters "O" on each side of the oxygen bag, and "H" on the sides of the coal gas or hydrogen bag.

It will usually be found in the case of two similar bags devoted respectively to oxygen and hydrogen that the one used for oxygen will be quite worn out and unserviceable through leakage before the other bag shows any deterioration whatever. Hence it is obvious that oxygen has a greater corrosive action on the indiarubber than coal gas. This destructiveness is said to be due to the chlorine gas which is evolved from the chemicals in the retort in company with the oxygen, and careful operators hence add powdered chalk, lime, or potash to the water contained in the "cooler," with the view of absorbing this obnoxious chlorine. I believe that the water which is carried over from the cooler into the gas bag, when the gas is generating very fast and the liquid in the purifier is in furious commotion, helps the bag to decay. The water once in the bag cannot evaporate, and it keeps the interior surface permanently damp. It is a good plan when making oxygen to have the bag on a table, and the cooler on the

floor. Any drops of water that may be forced from the cooler into the rubber tube by the pressure of gas will then flow back into the vessel when the current of gas becomes weaker.

Temperature has a great influence upon the durability of gas bags. I once had a large new bag of good quality rendered unserviceable through corrosion in *six weeks*. This occurred in the heat of summer, and the bag contained oxygen. A similar bag containing coal gas was sound at the end of that period. Hence gas bags are rarely used in hot countries, such as India, as the expense of maintenance is so great. During frosty weather the bags do not deteriorate at all, or else they do so very slowly indeed. If the question arises as to whether any surplus oxygen that may be left after an exhibition is to be used or not the temperature should be taken into account. If the weather is frosty, keep the gas by all means; if it is warm, it will be better policy to empty the gas bag. It is a good rule to put bags containing oxygen in the coolest place available.

When the limelight first came into use it was customary to put both the oxygen and the hydrogen into one bag. This method certainly had the advantage of simplicity, as no adjusting of the jet taps was required; but the explosions that occurred induced those in charge, out of consideration for their personal safety, to adopt the system of separate bags for each gas. It is possible to work a mixed gas jet with one bag containing the two gases without rendering the services of the coroner necessary, the points to be observed being the use of a small aperture in the jet nozzle, and plenty of pressure on the gas bag; however, such a system is more dangerous than the use of ether tanks, which, as most lanternists are aware, are quite capable of being blown up.

I know a gentleman who some years ago gave a lantern exhibition to a crowded audience; he was using the mixed gas jets, and had his two bags of oxygen and coal gas in the pressure boards as usual. When half of the slides had been shown he was startled to find, after adjusting the two taps of a jet, that he had turned one completely off and the light was still burning brilliantly! It was plain, owing to some mistake made in the filling of his gas bags, that one of them contained a highly explosive compound. He was thus on the horns of a dilemma; either he must proceed with the exhibition at the risk of the lives of those near the apparatus, or else an awkward and undignified "five minutes' interval" must be put into the exhibition. He chose the latter, and quickly turned the gas off at the jet; the audience sat in a state of surprise and total darkness for a few minutes, but, after a while, a change of bags was effected, and the exhibition was continued.

If any one who reads this article should find himself in a similar predicament, I would advise him to adopt the same plan—unless he is alone, and has his life heavily insured, in which case prudence is, perhaps, not so essential.

ALBERT WM. SCOTT.

LANDSCAPE PHOTOGRAPHY.

[A Communication to the Aberdeen and North of Scotland Amateur Photographic Association.]

My aim in the short paper I am about to read will be to lay before you a few things in connection with landscape photography. This refers to photography as practised outside a studio, and I purpose dealing only with it from the practical side, so that while I refer to it as I have observed it practised by many amateurs, gentlemen present will kindly bear in mind I do so from the point occupied by one interested in securing the best arrangement of subject under the most suitable light and conditions essential to success.

That photography has a charm for many is evident from the great number of cameras I come across in my wanderings, the owners thereof firing off snap shots on every conceivable subject, and under what appears to me as a rule—unfavourable conditions. Yet there is a certain amount of pleasure even in this, though only the ghost of a picture is developed, as better things can be hoped for the next opportunity. However, I have seen many exquisite pictures by amateur gentlemen who practice photography purely for pleasure, indeed, very much superior to the work of some professionals; but I don't think you'll find they go in for trying everything instantaneously. I am often approached in a knowing sort of way, "Ah! working the instantaneous process, I suppose?" and great surprise is expressed when I answer in the negative; but since the use of dry plates became general, the one idea of many appears to me to do all subjects instantaneously. The results are disappointing, even when good subjects are attempted, in a hazy, dull day; how much more when done as I saw during the last summer at Rothesay pier. A gentleman, one fine afternoon, from the deck of the "Columba," directed his camera towards the sun in his endeavours to secure a view of the town. Everything was in deep shadow, while the strong sunlight appeared

to intensify the smoke that hung over the many chimneys. I refer to this as one instance out of many I could bring up of the indefinite ideas that exist as to what constitutes a favourable light for securing a good picture. Had the camera, in this case, been directed in nearly an opposite direction, something good might have been got of Rothesay Bay, with the Cowal Hills in the distance, while a lugsail boat or a passing steamer could have been utilised to break up the expanse of water.

Then the attempt to overtake something beyond the capacity of either camera or lens, such as a tall steeple. With his back to a wall and the camera turned up to nearly the angle of forty-five, I have seen a gentleman vainly hoping to make a picture; add to this the fact that the sun was directly at his back, which gave the steeple without a trace of shadow on it.

Then, again, some run after animals, and wonder why their instantaneous plates develop almost clear glass, and express surprise they cannot turn out something worth a medal, since some other body does very fine studies of animals.

In connection with the laudable desire to do something good, an incident comes to my mind. While working in St. Andrew's, a gentleman approached me one day and asked if I could direct him to any good subjects in the district. I replied to the effect that I thought he was in the midst of a great variety of very good subjects, adding there is the cathedral, the castle, houses ancient and modern, while there is the ever-changing sea, with rocks, waves, boats, and indeed better material than could be found in many places. He shook his head, and said that was not the sort of thing he wanted; but pulling from his pocket a book treating on composition pictures, added, "It's something of this sort I want." Rather advanced for a beginner, I thought; however, I remarked, "There is plenty of scope for your hobby all round. There is life of every sort, industry and indolence among all classes, from the aristocrat golfing on the links, to fisher folks busily baiting their lines or lounging at the street corners, with their hands plunged into the unfathomable depths of their pockets—this, with creels, boats, lines, and heaps of mussels, is surely variety enough; but your difficulty will be to secure the good-will of your subjects, which is most important." Whether or not he made up his mind to attempt this I cannot say, but I found him dodging about after me as if he had got new light on some of the subjects he did not think worth attempting before.

However, there are one or two elements of character I consider indispensable to success in photography. I pass very lightly over the fact that any one who is enthusiastic will know the advantage of early rising; many a good view is got when a large proportion of the inhabitants are snoring in bed. Patience, with perseverance, is said to work wonders, and there will be many opportunities for carrying these into practice, if you would make the best of every subject.

When doing work about a town, smoke is very troublesome, and often entails a weary wait. Then a fine reflection may often be secured by exercising a little patience and watching for a brief lull, not to speak of the advantage of quietness when foliage breaks up the foreground.

Then in order to secure the best light, it is often a great advantage to wait until the sun moves round a little, or, more correctly, "the earth moves round." Of course there are many occasions when it is manifestly useless to wait for the calm moment, and in such a case it is wise to look for a subject unaffected by wind. But in any case be deliberate in choosing a point, and, when decided on, be deliberate in fixing up the camera and exposing, or you may find yourself uncapping your lens before the plate is uncovered; or some fine day you'll be exposing the same plate twice, and find out perhaps after all that if a little more care had been exercised a much more effective point, and that in a far better light, could have been secured.

This brings us to the importance of method in working, and in this connection it will be wise to run over the necessary apparatus, with which it is well to be on very familiar terms. This will prevent us going into the country some day minus the camera screw, or perhaps the tripod top, without which we would miserably fail. Have a place for everything, and run over in your mind the operation of fixing up the camera for work, and exposing a plate, in order to satisfy yourself that nothing is wanting.

This will bring us to speak of apparatus, of which there is great variety to select from. Not the least important is the stand, as many a good view is lost through a rickety stand. Most of the stands of the folding pattern have this fault, on account of having only a single limb from the joint downward. I have with me an improved folding stand you may inspect. A spirit-level is another necessary in getting correct pictures where straight lines come in.

The camera and slide I'll suppose you have very carefully inspected, lest any stray light may come in and the unfortunate plate maker be

blamed for sending you bad plates, while the fault lies with the camera not being sufficiently light-tight. Inspect every movement, such as sliding front, with the lens screwed on and capped. Throw up or remove the focussing screen, and, with the camera placed in bright sunshine, look through as if about to focus, with the cloth carefully adjusted so as to keep out all light from behind, and you may, by turning round the camera, discover some little chink you never dreamt of. However, it is always well to work with the cloth carefully adjusted, so as to screen the camera and lens as much as possible. A swing back is also a very useful arrangement, but requires to be very carefully adjusted.

"What lens do you use?" is a question very frequently asked of me. Well, any good lens will do, providing you don't attempt too much with it. Confine your lens to covering a plate the diagonal measurement of which is equivalent to its focal length, excepting when you have a lens especially made to cover a larger plate, such as a wide-angle rectilinear. A single lens is good for general landscapes, but many of the single lenses that are going are of a small diameter, and consequently slow. However, for many subjects, this is no objection, but there is satisfaction in having a good lens. A rapid rectilinear is doubly useful.

Now supposing the slides have been carefully inspected, dusted, and charged with plates, you will think about trying something. Although it is quite possible to go through the whole operation mechanically, since the dealers send out printed instructions of the plates being so sensitive, you can expose, bring home, and with so much out of bottle No. 1, and so much out of No. 2, you develop so many minutes, and everything is bound to come out right. Well, perhaps they may, and no doubt this accounts for some—when first attempting photography—producing one or two wonderful plates; but how they got them is a mystery to themselves, for they say we cannot do the same now.

We will begin by not attempting anything very great. A friend's house is always a handy subject, and houses being all pretty much alike we will consider how we can set it off, for we will not be satisfied with planting our camera right in front of it, and filling the plate with the front or front and gable walls. Are there any trees about? as, if possible, we must get them introduced, so as to make the picture. Of course it is well, in most cases, to get sunshine, particularly if the building is dark, of which, by the way, there are not many about Aberdeen. But with the most important part of the house in sunshine, and just enough shadow to give relief, we notice if the trees are still before exposing, which must be done deliberately and sufficiently long to get details in all the shadows without solarising the high lights.

Suppose we go to the country a bit, and try a different style of subject. It is well to remember, in this connection, what constitutes a photographic picture. It is not colour, but light and shade; and subjects that appear to many as effective pictures are of no use for photographing. We want form, and that must be effectively lighted. For general landscapes we want a clear day with bright sunshine.

The selecting of a good plate is important. The rules applicable in fixing a good point for sketching hold good in photography, not forgetting that colour is nowhere. Though in sketching anything we fancy may be introduced, in photography we must adapt ourselves to things as they exist, or very nearly so. Look at a good engraving or a good photograph, and while making up your mind not to copy the photograph, you may be sure you cannot exactly reproduce the engraving, but there is something to be learnt from both, and turned to good account the first opportunity for selecting a point. If there are distant hills in the landscape, they will probably show up best if the sun does not shine on them when exposing, though by all means have sunshine on the foreground and the middle distance, and avoid having very large objects in the foreground, or the distant hill will look too diminutive. Be always ready to take advantage of water, trees, rocks, loose branches, tree roots, or anything at hand to break up a smooth foreground.

If a waterfall is the subject chosen, or if the nature of the day warrants this—for all arrangements in photography are subject to the weather, a quiet sunless day will suit, and in many cases will be found preferably to a day of brilliant sunshine, as in deep gullies and shady glens bright sunshine shows such heavy black shadows that, in order to expose them sufficiently, the high lights are all solarised, but with a quiet, even a hazy day, we can get every leaf, every twig and fern, if sufficient exposure be given.

On such a day as this, some of the beautiful weeping birches on Deeside may be got; haze in the distance will help to make the tree stand out, if you cannot show it with water in the background: so you see there are great varieties of subjects in a day's outing, and if the weather prove unsuitable for one, we may fall back on another.

The beauty of cloud effects, when taken in connection with water, I feel confident is appreciated by all who possess a camera, and, being near the sea, there is abundant opportunity of securing something in this way. For this we must have a cloudy day, but not too many clouds, and, with the sun ahead of us, we can watch for the effective moment and expose quickly. Avoid having the sun blazing immediately in front, though a ray striking the water in the distance enlivens the picture wonderfully.

When photographing on a street or on a road, there is often the objectionable accompaniment of a great stretch of white foreground. The shadow of a tree helps in a case of this kind, if we can secure it; failing this, the shadow of a building. A few buckets of water, judiciously spilt, will often work wonders. But the greatest difficulty in street views is mobs of people who want to be "looked." A few coppers may dislodge youngsters, but it is not an easy matter and often very tantalising, when a favourable opportunity occurs, to get some grocer's or butcher's boy, with a white garment of some sort and a big basket, stand up some twenty or thirty feet from the camera, when you know by experience that, however short the exposure may be, he'll keep moving. Patience may weary out a few, and this, with a little tact, may overcome the difficulty.

Cattle may be got on a sunless day even better than on a day of brilliant sunlight, and that with a very short exposure.

Portraiture may also receive a share of attention, and it is possible to turn out good pictures without a specially built studio. The great objection to portraits taken out-of-doors is they are flat. Now this may be got over to a great extent by adopting the course I am about to suggest. Avoid setting down your subject back to the wall and facing an expanse of open sky, as this shows the face without a trace of shadow. Reverse the order of things, and set your subject a few yards outside, say the back-door, in a diffused light. If you have no special background, the wall of some outhouse will serve this purpose, and its distance will ensure its being soft. Keep the camera a few feet inside the door, just in the passage. Of course, when making this arrangement, you must necessarily discern when you have got sufficient shadow; a slight movement either to the right or the left, or a little farther from or nearer the doorway, makes a great difference, and with care a fine round picture can be secured in this way.

"But what exposure do you give?" is so often asked that I suppose I must say something about it, though to fix anything definite is misleading, as no two subjects are exactly alike, and the same subject would require longer or shorter exposure at different hours of the day. An improperly lighted subject will not show up well, whatever care you bestow on it, and one with heavy, dark shadows in the immediate foreground, and the distance flatly lighted with brilliant sunshine, need not be attempted, as if you expose the foreground enough the distance is lost, or get the distance right and the foreground is clear glass. Take such without sun altogether, if you cannot get the light and shade sufficiently distributed. Also avoid exposing when the sun is at the point that leaves you without any shadow, and avoid exposing when the sun is so far ahead of you that everything is in shadow excepting the house-roofs and the level road. As exposure plays a very important part in the production of a good print, it is well that this should be sufficiently long to bring out all details in the shadows, and ought to be so timed as to allow of development being carried out without either forcing or restraining. An under-exposed plate is waste, excepting in so far as you learn to expose more correctly the next time. A full exposure—that is, an exposure that admits of a considerably smaller proportion of ammonia being used than the plate can bear—will allow you greater control, and this is a feature I believe very much overlooked in dry-plate photography. It is so much out of this bottle and so much out of that, and develops so long—well, you may as well put them into a churn and turn a handle. Just see how hard some pictures turn out, and a nice soft thing might have been got had the development been regulated by a former subject. Then be careful to develop until all details are out, which, in many subjects, means that you don't make up your developing solution of the strength that would show your high lights as dense as a board by the time the details in the shadows come out. Many a good picture is hopelessly spoiled in development, while many an over-exposed plate may be saved with care and patience.

Those who are familiar with the working of the collodion process must have noticed there is a difference between a collodion and a gelatine negative, to such an extent as I believe may never yet have been fully taken into account. For instance, a gelatine plate that looks like a good old collodion plate is almost useless for ordinary printing, whereas a gelatine plate, that, judging by a collodion plate, would be useless, prints amazingly well, and leads many to be satisfied with, I think, too thin negatives.

I have always developed with ammonia and pyro, and find a full exposure gives the best picture, using as little bromide as possible. After fixing I prefer immersing the plate in a solution of protosulphate of iron and citric acid, as, in my estimation, it removes yellowness better than anything else, so after washing thoroughly and drying, you will have time to spot and prepare for printing, in connection with which I see Mr. Sang is expected by-and-by to clear away all the difficulties, and make this process easy and delightful to yourselves and your friends, who will look upon the productions of your camera many days hence.

ALEX. M. RIDDLE.

PEELING OF PRINTS.

UNDER the heading of "Answers to Correspondents" which appeared on New Year's Eve, "H. M." brings under notice an experience in practice which is not by any means singular at this season of the year, as doubtless many of the readers of this JOURNAL can testify.

The earliest recollection the writer has of the difficulty alluded to being forcibly impressed upon him, occurred during a brief sojourn among the Redskins of the great North West, as far back as the memorable freeze-up of 1868, and in a region where half the year is usually accreted with very low temperatures. Here it became necessary to melt ice before print washing operations could be commenced, and it was by no means unusual to find photographs, which were under this somewhat crude system of being freed from deleterious agents, fixed securely in a solid block of ice when looked at on the following morning. With extreme care, and a prolonged application of heat, a proportion of the number could be saved from total destruction of the kind suggested by your correspondent; but these, which were decidedly in the minority, showed unmistakable evidence of unfair usage. Coming to recent events, it may be mentioned that a short time ago complaints of a similar character were rife in Aberdeen, Glasgow, and other places in the North, whereby many hundreds of prints became damaged and totally unfit for sale, from no other cause than that induced by the lowness of temperature then prevailing. Some of these specimens were shown at a meeting of the Photographic Society of Great Britain, but as the majority of the members present evidently had not been in the habit of carrying on the pursuit of silver printing under difficulties, they were unable to arrive at a satisfactory solution of the enigma. Possibly another reason which militated against the real cause being discovered on that occasion was the circumstance that the examples were for the most part 8x5 photographs of, in all other respects, an exceptionally high character, the initials thereon being a sufficient guarantee that no ordinary preventable causes would be permitted to step in to mar the attainment of perfection in photographic presentments of nature.

Sufficient evidence has now been adduced to prove a case for your correspondent "H. M." Now let us for a moment consider how these pernicious effects may be easily produced, and the remedy will at once become suggestive.

Like "H. M.," a good many other photographers sensitise their *double albumenised paper on a sixty-grain solution of silver nitrate*, and leave the prints resulting therefrom in some vessel of water all night for the purpose of washing, and so far there does not appear to be any real objection to such a method of treatment; but "H. M." has not yet stated to what extent he has contributed to the failure by the use of hot solutions in toning, &c., thereby imparting a more than ordinary degree of softness to the size which his double albumenised paper contains. If the bonds of adhesiveness, which are intended to retain two surfaces in tolerably perfect contact, become loosened mechanically, or by any other means, then it is not difficult to imagine that the whole, or part of the surface of any print may detach from its former support when other and stronger forces become exerted to bring about such a result.

A layer of water, no matter how thin it be, in contracting to form a fine surface of ice, is a force capable of doing all that has been complained of by "H. M.," and others, when the conditions are most favourable. We know that a print, when removed from a vessel of water to an atmosphere in which the temperature does not exceed 32° Fahr., will of necessity very soon support a layer of ice upon each of its surfaces, and if permitted to remelt and dry in a warmer position, without being handled, might turn out all right; but place one print in contact with another when in a semi-frozen state, blot such prints or use physical force in any way, and the ice crystallised within the cells containing the silver image, as well as in the porous paper, will, without further ado, proceed to exert its influence in detaching the brilliant or more highly polished surface from that which underlies it, always, of course, leaving a vigorous image

beneath, provided the operation of sensitising has been sufficiently prolonged to ensure the silver solution having penetrated into the body of the paper situated beyond the albumen coating. For whether the sizing used in the manufacture of the photographic paper be of the nature of starch or gelatine, we know it to be capable of becoming sensitive to light when silver chloride is formed therein, with or without an excess of silver nitrate, and in such a condition it is possible to obtain an image by the aid of daylight in all respects as forcible as we are in the habit of getting with single or double albumenised paper brought under the influence of similar conditions.

ESQUIMAUX.

THE USE OF THE HYDROMETER IN PHOTOGRAPHY.

IN every process of manufacturing that involves the making of solutions of salts of known strength, or where it is necessary to mix and dilute solutions to a given value, the hydrometer is the most useful instrument to place in the hands of the operator. This is pre-eminently the case in chemical manufacturing, as well as in pharmacy and the compounding of alcoholic beverages; and it has often been a problem with us why the photographer does not use the hydrometer to assist him in mixing his developers and other solutions. Perhaps the neglect to use such a useful instrument may be put down to the fact that few photographers stop to think of its merits. As a simple statement of the principles upon which the hydrometer is constructed and works, and a few indications of its manner of use, may prove interesting, we have thought it worth while to call the attention of our readers to the subject.

The hydrometer consists of a glass tube with two bulbs near one end, the lower one being loaded with shot or mercury. It is so constructed that when placed in water it will float in a perpendicular position, which essential function is secured by the shot or mercury in the lower bulb. The principle upon which it acts, in determining the specific gravity or comparative weight of a liquid referred to water, is one which was discovered by the Greek philosopher, Archimedes, that a solid body placed in any liquid will sink in that liquid until it has displaced its own weight of the liquid. The hydrometer, therefore, must be of such a form that it will float in water; and how it will float, that is, how much of the stem will rise out of the water, will depend upon the purposes for which it is desired to use it. According to the principle of Archimedes, a heavy liquid will cause the hydrometer to float higher than a light one. It is, therefore, necessary in this case to make it float in water as deep as is convenient to handle it, and to mark the tube at the point where it stands under these circumstances. When such an instrument is placed in a liquid heavier than water, more of the tube will float above the fluid than when it is placed in water. In the case of liquids lighter than water (alcohol, ether, &c.), an instrument graduated as above stated would be useless, for the reason that it would be too heavy; it could not displace its own weight of the liquid, and therefore it would sink. In this latter case the tube must be so weighted that as much of it will stand out of water as will secure a vertical position for it, and the place where it so stands in water is marked, as in the case of the instrument for heavy liquids. From the position of this water-level mark it is obvious that when this last hydrometer is placed in a liquid lighter than water it will sink lower in that liquid. These statements may appear very elementary to many of our readers; but we are pretty sure that a great many of them have never given the subject a thought, and have failed to realise the value of one of the most useful pieces of apparatus that can be placed in their hands.

We have stated above how the zero point, the level at which the hydrometer stands in water, is determined, from the use that is to be made of the instrument. The next step is the nature and meaning of the divisions on the tube, and here an arbitrary method of marking is as good as any other, provided the value of the divisions are known. Of all the hydrometers ever invented, that devised by Beaume, a French apothecary, is the most popular and the simplest to use. The method he adopted for determining the divisions on the scale was to place the hydrometer into a solution of common salt containing fifteen parts of salt and eighty-five parts of water; and the position on the tube where the instrument floated in the solution he marked 15. The tube between this point and the zero mark he divided into fifteen equal parts, and continued the division below the 15 mark in exactly the same manner. These divisions are called degrees Beaume, and while they do not exactly represent what Beaume sought to establish, percentages of salt in the solution mentioned, they serve as an arbitrary scale to use for any purpose where a hydrometer can be utilised.

All the Beaume hydrometers now made are constructed upon the principles we have indicated above, and if we know their value for any given solution we can determine in an instant the specific gravity of that solution, and also the quantity of valuable material in it.

Photographers have already in their hands a hydrometer—the actinohydrometer—for determining the value of their silver baths; but this instrument is devoted to a special purpose, and our idea is that the hydrometer shall be used for all classes of photographic solutions where their value should be known by the operator. Take, for example, the mixing of the ferrous-oxalate developer. We are told to use a saturated

solution of the iron salt and a saturated solution of oxalate; but who knows that the solutions are saturated unless special precautions are taken to secure such a result? With a Beaume hydrometer this can be determined in an instant, from the fact that a saturated solution of ferrous sulphate stands at 27 degrees Beaume, and a saturated solution of potassium oxalate at 30 degrees. Hyposulphite of soda solution is saturated when the Beaume hydrometer stands at 40 degrees, and perfectly definite figures can be found for each salt used by the photographer. Furthermore, solutions having a definite strength, say, one to four, or such figures, can also be most readily determined by the use of the hydrometer. One word of caution only is necessary; that is, all solutions should be at ordinary temperatures, 60 to 65 degrees F., the instruments being graduated for this purpose only.

We have called attention to the use of the hydrometer that photographers may have a means of knowing more thoroughly what they are doing with their solutions. We are well aware there are many objections to the use of the Beaume scale, but to-day it is in use in every large chemical works on the Continent of Europe and in the United States, and as it is to be found in the market of considerable accuracy, we consider it the best and most useful instrument for the purposes we have indicated. Should our readers think it of sufficient interest, we shall publish, in the future, tables giving the degrees Beaume for solutions of the more ordinary salts used in photography.

—Anthony's Bulletin.

STELLAR PHOTOGRAPHY.

PHOTOGRAPHY has of late years become so completely the handmaid of Science, that we cannot be surprised at any of its most recent developments. The microscopist is no longer dependent on the pencil of the draughtsman for accurate representations of the objects under his lens, and the passing eclipse is secured for future study by the photographer who has become so important an assistant on that critical occasion. The astronomer sweeps the heavens with aids at his command which the Herschels never dreamt of possessing; and Dr. Huggins only lately secured a plate of the sun's corona under circumstances which bid fair to render a natural eclipse no longer necessary for the student of solar physics. A close examination of the moon's photographs have revealed hills and valleys and dismal craters which the observer did not at first note through the telescope, until, as Professor Newcomb lately declared, the surface of that planet is better mapped than many sections of the United States. But it has been left to M. Struve to confirm by means of actual observation a fact which, for several months, had rested on the authority of the photographic plate alone. In November last the Brothers Henry succeeded in obtaining a photograph of the Pleiades. In itself this was a sufficiently notable feat, for though Rutherford and other astronomers have succeeded in making photographic charts of the heavens—and one of the earliest applications of the art was by Warren de la Rue taking an exceedingly sharp impression of the same group—the plates hitherto obtained were faulty in many respects. But what was most remarkable in the Henry plate was not the actual picture of the "Six Sisters," but the fact that an object hitherto unnoticed by the thousands of eager eyes who had scrutinised the constellation appeared in it. This was not Sterope, the "invisible one," whom the ancients fabled to have hid herself in shame, because she alone had married a mortal, and who is supposed to have existed in the form of a seventh star, which has gradually disappeared. What met the astonished gaze of the photographers was a large spiral nebula, apparently proceeding from the star Maia. Twice again, at the interval of three weeks, the constellation was photographed, and with a like result, the nebula invariably reappearing of the same form and in the same position. On examining a plate taken at the Harvard Observatory ten days before the one referred to, this identical nebula was noticed, but, in spite of the exertion of the Paris astronomers, assisted by their largest instruments, no sign of the nebula revealed by the lens could be detected. But M. Struve, of Pultova, having got his gigantic telescope into position, is at last able to report that he has actually seen what hitherto had to be taken on the credit of the photographic plates on which the Pleiades told their own story.

The interest of this revelation is twofold. It proves, in the first place, what a wealth of worlds still lies for the explorer of the heavens to discover, in spite of the vigils of all the watchers, from Job to Janssen. Scarcely a year elapses during which some new planetoid is not announced, and comets are so frequently coming into view that ignorant folk, who do not appreciate the scientific importance of these wanderers in space, are beginning to grow blasé with the news. Not long ago a new star appeared in the nebula of Andromeda, and now a fresh cluster of unknown and, for the time being, undetermined luminaries is revealed in the Pleiades. Several views of this region have already been figured. But it is strange that, with all the study devoted to the famous cluster, it has been left for the photographic camera to tell what the most powerful telescopes had, up to the date of M. Struve's confirmation of the Henry photograph, failed to reveal. Yet each of the shining specks that make up the flocculent curl, which looks like a curdling fluid, is most probably a little star, imperceptible to the naked eye, simply because the rays of light proceeding from each of them are so blended with those from the stars in their close proximity, through the influence of irradiation, as to produce an effect

which can only be compared to a luminous mass. What is the exact nature of the new nebula is less important than the fact that it exists. Many nebulae are variable. The large irregular nebula which surrounds the star *Eta* Argus has been thought to be of this nature, and the great nebula in Orion is under a similar suspicion regarding its constancy of form. Others have vanished since the period when they were first noticed, while, on the other hand, there are nebulae which have appeared in places where no nebulousity had been noticed, though the space had been carefully scanned by observers who could scarcely have missed it. It is just possible that the new one may be of that nature, though the chances are against it. But what is of even greater interest is the circumstance under which it has been discovered. Now that photography is proved to be invaluable, not only as a recorder but as an observer, the field which it opens up seems boundless. A star millions of miles away takes its own portrait, though no human eye, aided or unaided, has been able to see it. The spectroscopic has enabled us to analyse the constituents of the sun and the other celestial bodies; and it is every day becoming more and more likely that before many years elapse we shall know almost as much about the chemistry of the fixed stars as we do at present regarding the envelopes of the sun, and its glowing atmosphere.

When photography first began to aid astronomy, the art was hampered by difficulties which no longer exist. Modern dry plates, which are not only cleanly but rapid, have obviated many of the mechanical obstacles which the old processes put in the way of the observer, so that the physicist has an entirely new tool at his disposal. Dr. Draper photographed the moon just forty-six years ago. But the first stellar photographs ever taken were those of *Alpha* Lyrae by the elder Bond, at the Harvard Observatory, in 1850. In 1857 his son carried similar investigations much further. At first, however, as the Brothers Pickering showed, in a paper read before a recent meeting of the American Academy of Sciences, they were unable to obtain clear images of stars of the second magnitude, while now it is possible to print those of the fourteenth. In other words, we can, owing mainly to the improvements in dry plates, transfer to paper an image produced by objects only a hundred-thousandth part as bright as formerly. By employing a new instrument, in which a photographic lens of eight inches aperture and forty-four inches focus is mounted equatorially and moved by clockwork, photographs of several different regions may be taken upon the same plate, and the stars distinguished by varying the exposures. By these means a new map of the sky may be secured, showing the position of the stars at any given moment, and thus securing for the astronomers of coming generations a record the importance of which it is impossible to exaggerate. Indeed, the only limit to the further extension of stellar photography is the sensitiveness of the dry plate, and as this limit is plainly not yet reached, Professor Pickering, of Harvard, who is actively engaged in these researches, is confident that even better results may be expected. All this is very different from the day when Warren de la Rue was essaying the portraiture of the Pleiades, or—by the aid of an equatorial mechanism for keeping the image of the moving planet for several minutes in the centre of the field of view of the telescope which moved along with it—succeeded in photographing Jupiter with his parallel zones. He even fixed on the collodion the rough surface of the planet Mars, and the wondrous image of the "belted ball" of Saturn. The moon is now almost as well photographed as a popular actress, and, it may be added, with a great deal more accuracy, for there is no "touching up" the negatives of Luna. However, as the pioneers in this field of research could not beg the moon "not to move, please," it was necessary for the telescope, at the focus in which the image was to be fixed, to move at exactly the same rate as the object photographed, so that mechanical accuracy was hard to obtain. These difficulties are now all but historical. The almost instantaneous gelatine plate, more sensitive than the retina, has made the astronomer's task no longer so hard, while such results as those just obtained impart to his pursuit all the excitement of a scientific lottery.

Department for Experienced Photographers.

EMULSION PHOTOGRAPHY.

Assuming the reader of this class of articles to be quite unacquainted with photography, we open the series by an elementary explanation concerning emulsion photography.

The sensitive material in a plate is usually bromide, chloride, or iodide of silver embedded in some suitable vehicle, such as collodion, albumen, or gelatine. Albumen was the medium in which it was at first formed, and the sensitive film was prepared by mixing with it a small proportion of iodide of potassium or of ammonium, which was then spread upon glass and allowed to dry. The plate thus coated was immersed in a solution of nitrate of silver, by which the silver combined with the iodine, forming iodide of silver throughout the interstices of the film, the potassium or ammonium combining with the nitric acid thus liberated and forming nitrate of potash, which, being soluble in water, was thus lost sight of. Not so, however, the iodide of silver,

which, being of a light yellow colour, and insoluble in water, remained in the film, to which it imparts a creamy appearance.

Seeing that plates prepared in the manner just outlined were used while wet, especially when collodion formed the vehicle in which the insoluble silver salt was formed, this method of working was known as the wet collodion process. But if the iodide (or other insoluble salt) of silver be the real energetic material which forms the photograph, why, it may be said, not make up a quantity by itself, and then stir it up among the liquid that is to serve as a vehicle? This was done many years ago, and from its thus forming an emulsion arose the term *emulsion photography*. A photographic emulsion therefore is nothing more or less than a solution of albumen, gelatine, or collodion, containing, mixed up with it, the sensitive salts (which are none the less salts because they are amorphous opaque matter) of which the image is eventually composed, after having been submitted to the action of light. The terms "collodion emulsion" or "gelatine emulsion" merely indicate the vehicle, and a gelatine or collodion emulsion plate is one coated with an emulsion formed of one or the other vehicle.

When a bromide of silver alone is cruised in the manner indicated, then is it termed a *gelatino-bromide* or *collodio-bromide* plate or process, and so forth with chloride and iodide. But as chlorine, bromine, and iodine are known in chemistry as halogens, they are not unfrequently spoken of in this connection as the *haloid salts of silver*.

Sensitive emulsion may be applied to paper (for being printed on in the usual way) as well as to glass. There are two systems of emulsion for paper; one in which the surface darkens directly under the light, the other requiring the aid of a developing solution. Paper coated according to the requirements of both these systems are now commercial productions and may be readily obtained everywhere. As a vehicle in which to emulsify the sensitive salt, collodion possesses a great advantage over gelatine, inasmuch as it is always ready for use; and from the great rapidity with which the film sets, it can be employed for the extemporaneous preparation of plates which will be ready for use almost immediately afterwards, or which, if allowed time to dry, will keep good for a long period. But gelatine in turn possesses an advantage over collodion on account of the greater hardness of the film and the superior sensitiveness. For the photographer whose aim is merely to produce a few plates now and again by artificial light in the evenings, the collodion emulsion, being always ready for use, will afford exceptional advantages.

RECENT PATENTS.

PATENTS COMPLETED.

A NEW OR IMPROVED POCKET PHOTOGRAPHIC CAMERA.

No. 8654. EDWIN MARTIN KNIGHT, 148, Cheapside, London, and GEORGE HENRY KNIGHT, 11, Bernard-street, Russell-square, London.—*July 1, 1886.* This invention relates to a new or improved camera for photographing, specially designed for portability and storage in the pocket, and consists of a combination of sensitive plate and a pin-hole lens. The latter is closed or sealed from the light before and after use, together with a containing and folding camera, the whole being so designed as to fold flat or letter-like in form, is produced at very small cost, and is specially designed for storage in the pocket.

According to this our said invention, we construct the sides, top and bottom, or "bellows" of the camera, of paper, glazed calico, or other cheap light and readily folded material, the front being preferably of cardboard, and in the centre of which is a hole, behind which hole and on the back of the cardboard forming the front of the camera is a pin-hole lens, the hole and lens being closed or covered by an adhesive wafer or cover, which can be readily removed. The rear end of the bellows is so cut and folded as to form a holding receptacle for the sensitive plate. The method of use is as follows:—The pin-hole lens being closed by the adhesive cover or wafer, and the sensitive plate placed in position, the whole can be pressed flat and placed in the pocket until required; whereon the bellows will be extended and the cover removed from the pin-hole lens, and as soon as exposed a sufficient time the adhesive cover or wafer will be applied over the lens hole, and the whole be pressed flat and returned to the pocket for after "development" at leisure. It will be understood that a number of the improved apparatus may be compressed into the space of a few inches.

The claim is:—The folding and expanding camera constructed as above described, and in combination with a pin-hole lens and sensitive plate, as above described, and illustrated by annexed drawings.

AMATEUR PHOTOGRAPHIC ASSOCIATION OF VICTORIA.—The following list was received too late for the ALMANAC:—*President*: J. H. Browning, M.D.—*Vice-Presidents*: J. McEwan and E. C. Bell.—*Hon. Secretary*: J. H. Harvey.—*Hon. Treasurer*: J. J. Fenton.—*Hon. Librarian*: E. A. Walker.—*Hon. Custodian*: E. W. Purton.—*Committee*: E. J. Hughes, J. Lang, J. Mulvaney, F. A. Kernot. Meets at Royal Society's Hall, Melbourne, on the second Tuesday in each month. Amateurs from all parts of the world made welcome, and any visiting Victoria are invited to communicate with the Hon. Secretary at the above address.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, December 30, at the usual weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. W. H. Prestwich presided.

Mr. J. B. B. Wellington exhibited some carbon pictures upon opal, as examples of a class of photographic work suitable for presents at this season.

Mr. A. Cowan exhibited some sensitometer prints, indicating that gas flames charged with "albo-carbon" had four times more actinic power than without it.

The question was asked what was the best way to render paper largely impervious to alcoholic liquids.

Mr. A. HADDON suggested first treating the paper with gelatine and chrome alum.

Mr. J. TRAILL TAYLOR asked why coagulated albumen would not do.

Mr. WELLINGTON had tried soaking plates in chloride of sodium after exposure and before development, as recommended by French operators; in every case, and with whatever developer he used, it slowed the plate, as tested by the sensitometer, and did not give a better image.

The question was asked what was the best mountant to prevent cockling.

Mr. A. L. HENDERSON responded that indiarubber was the best.

Mr. TAYLOR said that the indiarubber became worthless in a few years. An alcoholic solution of glue or gelatine with a minimum of water was good.

Mr. HENDERSON had obtained as good results with ordinary plates as with the orthochromatic plates in the market.

Mr. W. M. ASHMAN said that the two kinds of plates had been publicly tested by the South London Photographic Society in the hall of the Society of Arts, and Dixon & Gray's orthochromatic plates gave by artificial light the same results in six seconds that ordinary plates gave in two minutes.

Mr. TAYLOR referred to a letter by Mr. Wellington published in these pages, and asked what was the position in relation to the patent for the use of eosine in orthochromatic plates.

The CHAIRMAN thought that to be a question for the law courts.

Mr. HENDERSON handed to the Curator some ready-sensitised paper to be kept in his custody, and to be returned to the Association after the lapse of one month; he said that it was advertised to keep for nine months, and had just been sent to him.

Mr. F. A. BRIDGE had taken home one of the packets of paper given to that Association some months ago, and spoken about at a recent meeting by Mr. Henderson; he (the speaker) opened his packet two or three days ago, and found slight but evenly distributed discolouration, as in the specimens he now produced before them. He had executed some prints upon the paper, and they could see they were fairly good, although not such as he would like to send out to the public. Altogether he thought Mr. Henderson's recent remarks about the paper to be hardly fair to the maker.

Mr. HENDERSON responded that on the occasion mentioned he had stated that he had not kept the sheets in their wrapper of paraffined paper. There was nothing to equal freshly-sensitised paper.

Mr. W. ENGLAND exhibited a cheap German instrument for testing milk, somewhat resembling a circular photometer in appearance, and which, he said, might perhaps be of photographic use.

Mr. TAYLOR said that it had been suggested to him that on ready-sensitised paper a thin film of sulphide of silver might gradually form, and that this accounted for perversity in toning.

Mr. A. HADDON stated that paper prepared upon an unsophisticated bath would after a time refuse to tone, and a neutral bath would tend to favour the formation of sulphide of silver; this would not be the case were the sensitising bath acid.

Mr. TAYLOR said that prepared paper treated with tartaric acid at the back would retain its whiteness for an indefinite period. He had some prepared with citric acid by Mr. J. R. Johnson at the time of the first establishment of the Autotype Company's works at Brixton, which paper he believed to be good yet. When he last opened the packet recently, when in America, the paper was all right and gave a good print.

The meeting then resolved itself into a committee for routine business purposes.

THE ROYAL INSTITUTION.

PROFESSOR DEWAR is now delivering a course of six lectures at the Royal Institution on *The Chemistry of Light and Photography*, and by last Tuesday he had reached the fourth of the series. Brilliant experimental illustrations are given, but as yet he has brought forward little which would be novel to the readers of these pages. His first, second, and third lectures were devoted to the phenomena of light. In one of them he exhibited a metallic mirror with a pattern which he had filed upon its back; it reflected light in the ordinary

way from its front surface, but when he slightly bent the mirror forwards or backwards the image upon its back appeared light or dark upon the screen; it was, in fact, an imitation of the magic mirror of the Japanese used in their religious services. In his first photographic experiment he placed his hand with extended fingers upon a sheet of glass covered with Balmah's luminous paint, and printed an image of his hand by means of a beam from the electric lamp; a black image of his hand then became visible upon a luminous background when the plate was exhibited in the dark. Last Tuesday he said that Wedgwood was the founder of modern photography, and first made known his results at a meeting of the Royal Institution in 1802. Professor Dewar here repeated Wedgwood's early experiment of taking a photograph upon white leather. He next took photographs by Niépce's bitumen process and by the Daguerreotype process. For these very slow processes he was obliged to use a most powerful electric arc light; the carbons were about an inch square.

The Comte and Comtesse de Paris and the Princess Helena were among those present at the lectures.

THE SOCIETY OF CHEMICAL INDUSTRY.

LAST Monday night, at a meeting of the above Society held at Burlington House, London, Mr. David Howard presided.

Mr. WATSON SMITH read a paper upon the new explosive, "Kinetite," a plastic material made of nitrobenzene, chlorate of potash, pentasulphide of antimony, and gun-cotton. In one of his experiments he pointed out that gun-cotton would dissolve in nitrobenzene, and that after the latter had taken up five per cent. thereof the solution could be boiled without danger of explosion.

Mr. John Spiller and Mr. Arnold Spiller were among those present at the meeting.

CAMERA CLUB.

ON Thursday evening, December 30, a paper on *Cameras and Field Apparatus* was read by Mr. H. H. O'Farrell [see page 8]. Mr. FRANCIS COBB occupied the chair, and, in introducing the discussion on the lecture, remarked that the subject had been covered in the most complete and interesting manner. He thought the old square form of cameras with fixed fronts was still the best in small sizes. As regards camera stands, he feared they were being made much too light now. Dark slides, too, were not what they might be. He knew of one that had been recently invented, constructed of steel, which, if brought up to its promise, would be a perfect double back. There might be danger of engendering heat, but it was perfectly safe as regards light.

Several visitors were present at the meeting, including Messrs. Gotz, Shew, and Martin, who explained the special features of their well-known cameras.

Dr. LINDSAY JOHNSON referred to the method explained by the lecturer for doing away with inner carriers in large-sized cameras, and remarked that this plan was largely adopted by Mr. Frith.

Mr. FERRERO thought that a long-focus camera was sometimes very necessary in the field, and useful for bringing into service the back combination of the rapid doublets. He exhibited a camera by Messrs. Sands & Hunter, in which the back was swung horizontally and vertically by rack-and-pinion movements.

Mr. E. COCKING, at the request of the Chairman, explained the construction and working of one of Brandel's photo-revolvers, which he had been kind enough to bring to the meeting.

Mr. GIFFORD pointed out that nothing had been said in regard to the fixing of the lens, and showed a simple means of securing the lens to the camera front, in which, instead of the usual screw, a bayonet catch was used and the lens put into position by a slight turn.

On Thursday evening, January 13, the subject for discussion will be *Negative Films*, when Surgeon-General Ranking will read a paper.

MANCHESTER PHOTOGRAPHIC SOCIETY.

LANTERN SECTION.

THE first popular meeting of the above Section was held in the large room in the Memorial Hall, Albert-square, December 22,—Mr. J. Schofield in the chair.

Mr. Abel Heywood, jun., contributed the first portion of the exhibition, which consisted of upwards of sixty slides from photographs taken by him during a tour in Hardanger Fjord, Norway, last summer.

The members' summer work was next shown, and consisted of upwards of one hundred and fifty views.

A vote of thanks was duly passed to Mr. Heywood for his excellent entertainment, and the meeting terminated. There was a large attendance.

Correspondence.

*** Correspondents should never write on both sides of the paper.

CAMERA CLUB CONFERENCE.

To the Editors.

GENTLEMEN,—May I ask you to insert this letter calling attention to particulars in connection with the General Photographic Conference to be held under the auspices of the Camera Club on the 8th of February next?

By the courtesy of the Council of the Society of Arts the use of its hall in John-street, Adelphi, has been obtained for the meeting.

Captain Abney will preside, and will also read a paper. Other papers are expected, contributed by Messrs. W. Adcock, W. K. Burton, A. Pringle, and J. Traill Taylor.—I am, yours, &c.,

Camera Club, 21, Bedford-street, W.C.,

G. DAVISON, Hon. Sec.

January 4, 1887.

BURNLEY PHOTOGRAPHIC EXHIBITION.

To the Editors.

GENTLEMEN,—The Burnley and District Amateur Photographic Society has decided to hold its Second Annual Exhibition of Photographs, open to the public, on January 27, 28, and 29. Last year we had a very successful exhibition, being crowded the whole time it was open, but we were rather short of exhibits. I now desire, through your columns, to appeal to my brothers in the art, amateur and professional, to kindly help us by sending a few of their works for exhibition. There are no prizes or competitions in any form. If any lady or gentleman who is willing so generously to help us would kindly send her and his name and address to me, I should be pleased to send further particulars.

The greatest care will be taken of exhibits, and special attention will be paid to repacking, and the cost of transit defrayed by the Society.—I am, yours, &c.,

WILLIAM SUTCLIFFE, Hon. Sec.

7, Bank Hall-terrace, Burnley.

THE PHOTOGRAPHIC SOCIETY.

To the Editors.

GENTLEMEN,—There is one paragraph in Mr. Bankart's letter in your issue of Friday, December 31, which may puzzle many. He writes:—"We see by the Catalogue that some of the more important business firms had from ten to twenty-one frames each exhibited, nine firms amongst them had one hundred and fourteen frames."

Possibly others have also been curious upon the matter, and have done what I have, namely, gone backwards and forwards through the Catalogue, the result being that I cannot total up the amount to the number of frames stated, whilst keeping in view the two factors in the sum, namely, the nine firms and the ten to twenty-one frames each.

I then tried the index, and with a glow of satisfaction began to think I had nearly unravelled the puzzle, as I there found a quantity of figures after certain names, but upon comparing the Catalogue with the index I discovered that I had been reckoning the apparatus numbers as frames, and so I got utterly lost, and gave up the search.—I am, yours, &c.,

OUTSIDE THE NINE.

ISOCHROMATIC PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—Your correspondents, Mr. W. H. Hyslop and Mr. Wellington, having called attention to the undoubted fact of Colonel Waterhouse being the first discoverer of the use of eosine as a colour sensitiser in photography, you will, perhaps, allow us to explain that in the Taillor & Clayton patent, dated January 8, 1883, the above fact is specially mentioned, the claim being for the application of eosine and its compounds to the gelatino-bromide process as distinct from the collodion process.

The novelty of this application is admitted by all who are conversant with the facts, including Colonel Waterhouse himself, whose experiments were exclusively confined to the latter process. We are advised that the patent is a perfectly valid one. This, however, is a question which can only be definitely settled in the law courts.—We are, yours, &c.,

B. J. EDWARDS & Co.

6, 7, 8, 9, and 10, The Grove, Hackney, London.

To the Editors.

GENTLEMEN,—Referring to your remarks in reference to Mr. W. H. Hyslop's letter in your issue of the 21st ultimo, there can be no doubt that the application of a known material to a new process, especially by a new method, is an invention which may constitute a valid patent.—I am, yours, &c.,

PATENT AGENT.

Suffolk House, Laurence Pountney-hill, Cannon-street, London, E.C., January 4, 1887.

Exchange Column.

*** No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange 12x10 single mahogany dark slide for whole-plate wide-angle lens.—Address, A. KNIGHTEN, Oakham.

Wanted, a bottle bichromate battery and Leclanche cell in exchange for a one-inch micro-objective with case.—Address, L. DIXON, High-street, Colne.

I will exchange a first-class head-rest or hive of bees for a good revolving stereoscope or Lancaster's 12x10 view lens.—Address, W. SAUNDERS, Dickleburgh, Scole.

Marion's universal camera, whole-plate, with double back and extra front, with rectilinear lens, and cash, for larger size tourist camera, good make, and lens; also ferrotype plates, envelopes, &c., for C.D.V. embossing frame, or, with cash, for half-plate folding camera with late improvements.—Address, BERLIN STUDIO, Old Kent-road, S.E.

I will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY from 1865 to 1880 for Dallmeyer's No. 1A wide-angle rectilinear lens or a good copying camera.—Address, J. H. MANN, Sandale, Doncaster.

Wanted, *Cassell's Technical Educator*, new edition, for photographic tools, mahogany half-plate camera, and many things, all in good condition.—Address, S. ARLIDGE, Photographer, Weedon, Northamptonshire.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a *NOM DE PLUME* as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

PHOTOGRAPHS REGISTERED:—

W. Kershaw, St. Anne's-on-Sea.—*Three photographs of Lifeboats, &c.*
J. H. T. Ellerbeck, Liverpool.—*Landscape view in Norway.*
R. W. Burdon, 45, St. George's-place, Canterbury.—*Portrait of Gamekeepers, &c.*
G. McKenzie, jun., Bridge of Weir.—*Portrait of Mr. McJanel.*

H. B. BERKELEY.—Received.

GEORGE E. WELLS (Franklin, N.Y.).—Not at present.

REV. GEORGE BLAIR (Ontario, Canada).—Your favour received. Thanks.

S. SMITH.—Write to Mr. W. Cobb, Woolwich, he may possibly supply your requirements.

A. B. C.—If you cannot otherwise recover the money your only remedy lies in the County Court.

J. WILSON.—We do not know the gentleman's address. Write to the Secretary of the Photographic Society of Great Britain.

J. S. B. S.—If you have anything new in optics to submit we shall be pleased to pass an opinion, whatever it may be worth.

ALBUMEN.—Moisture is doubtless the cause. If the prints be made as dry as they get in summer the surface will be as hard.

FIFTEEN-GUINEA SET.—The letter could not be published without your name being appended, which we think you would scarcely like.

A. W. J.—The paper having become damp and mildewed is now useless for albumenising. It will be a waste of time and material to use it.

J. A. W.—Rough drawing-paper suitable for coating with insoluble gelatine, for single transfer carbon printing, may be obtained from any artists' colourman. Whatman's or Hollingworth's answers quite well.

RAPER.—1. If the solution still contains any gold it will be advisable to add it to your other gold residues.—2. The lens in question is, no doubt, an old-fashioned single landscape lens. It will not be worth while to fit any other lens to it with a view to improvement.

B. S. inquires what is the best lens for taking instantaneous pictures three inches square with a pocket camera.—The best lens to employ is one of the "rapid" type of about four and a half inches focus. Such a lens will, or ought to, cover this size plate well with full aperture.

METALICUS.—Spence's "metal" is what is known as a sulphur sulphide. It is, or used to be, obtainable of Messrs. Spence & Co., 31, Lombard-street, E.C. The melting point is about 250° Fahr. It will be much more economical to purchase the metal than attempt to make it for yourself.

R. W. SIMMONS.—We have not retained the address; you can, however, overcome your difficulty in the same manner as we recommended our correspondent to overcome his, namely, to employ stronger solvents. Methylated solvents will do quite as well as any other for enamel collodion, provided they are of sufficient strength.

BEGINNER (Yorks.).—It is impossible to say where you have failed. If you send us one or two examples of your difficulty we can no doubt assist you. The process is really very simple when once understood. From the tone of your communication you appear to think the difficulties of working are very formidable. Such is not the case.

J. HICKS.—If you take the engraving to any picture restorer he will clean it for you for a small sum. Cleaning prints is not a really difficult operation. But, in the hands of one inexperienced, there is some little risk of injury to the original. "Plate paper," when wet, is far more difficult to handle than photographic paper; hence the risk.

C. A. M. W.—To reduce a negative on paper, place it in a weak solution of ferricyanide of potassium and hyposulphite of soda—say, three grains of the former to one ounce of a five per cent. solution of hypo, the solution being freshly prepared. Instead of developing each print separately, we advise you to do them in batches. We shall be glad to hear from you again.

F. G. S. says: "1. I am about to take a private house in a terrace (end one), and, as I am only a beginner, I do not like to build a studio to be a fixture, so thought of getting a portable studio, which, if I am not mistaken, can be removed after erection if requisite. Will you tell me how I must go to work?—2. There being six or more houses in the row, I am anxious to know whether the neighbours can in any way interfere with me in erecting a studio if I get permission to do so from the landlord. It will not overlook any one's premises except the gardens.—3. Can you inform me within a little the price of a good studio?"—1. If the studio is a portable one, and is not really attached to the ground or to any surrounding buildings, it can be removed at any time.—2. If you obtain the sanction of the landlord we presume the neighbours cannot interfere, provided the Local Board regulations are not infringed. Of course the next-door neighbour can erect any structure he chooses on his own ground so as to stop out your light, if he thinks fit, which is scarcely probable.—3. Better get an estimate from a local builder, or, if you wish for a second-hand studio, advertise for one.

ANTI-FAT.—If we understand the description rightly, the trouble does not proceed from grease in the gelatine. It may generally be overcome in the manipulation. Try the following method of coating:—Pour on to the plate about double the quantity of emulsion it is to retain, then dexterously shoot off the superfluity and quickly bring the plate to the horizontal position. Thanks for your friendly greetings.

J. J. writes: "1. I am thinking of getting a studio built, twenty feet long, ten feet wide, eight feet high; please tell me how much glass to put in and where to put it to get best results?—2. The studio will be near the road-side and people will be able to see in; will you tell me what to put on the glass, or should I use white muslin or what so as to get best results without making exposure much longer?—3. To use a whole-plate camera and quarter-plate lens will it take a longer exposure than using quarter-plate camera?"—In reply: 1. For that size studio four feet six at each end (roof and sides) opaque and the rest glass will answer very well.—2. The side next the road may be glazed with fluted glass. That will prevent passers-by seeing into the studio. Ground-glass will also answer the same purpose. Either plan will be better than muslin.—3. Certainly not.

BLUENOSE writes: "1. I have seen several references in THE BRITISH JOURNAL OF PHOTOGRAPHY to 'Willesden paper.' can you inform me if it is employed for building purposes, would it be suitable for covering a portable studio walls and roof, or roof only? I wish to build a portable studio for taking classes at colleges, &c., and want to make it as light as possible, and thought of making the roof at least of the paper, if suitable. Please advise me if it is suitable for such a purpose, and if very expensive. If suitable perhaps you could give me the address of parties interested, whom I might address for further particulars.—2. Can photo-erayons be made from scratched or spotted negatives? if so, how is the photo-crayon spotted, and with what materials? If you can give me any information on the above subjects I will be much obliged."—In reply: 1. Willesden paper is, we believe, not very extensively employed for permanent buildings; but it is very useful for purposes such as that of our correspondent. It may be had of different thicknesses, and it is not expensive. The address of the makers is Willesden Paper Works, Willesden, Middlesex.—2. In making photo-crayon pictures from scratched negatives the best plan is to touch out the scratches as neatly as possible in the negative, then what still shows in the picture may be repaired with water colour, as in ordinary spotting.

G. A. writes: "Please inform me what, in your opinion, is the cause of the camera being reflected in the enclosed print, under the following circumstances:—The parrot's cage was placed on a chair just outside the hall door, the hall behind being a particularly dark one, with no mirrors about. The lens used was 'rapid,' and the exposure two seconds. The day was bright, with no sun; snow was on the ground; the development showed that the plate had been properly exposed, and I am at my wits' end to account for the image of that confounded camera, the only explanation as yet offered being that it was jealous of the Poll. Is there any method by which the ghost of the camera could be erased, as the parrot is a pet in the house?"—The effect is very peculiar, but we cannot attribute it to a reflection of the camera. It rather appears as if the plate had received a prior exposure to some bright object. However, the remedy is what has now to be considered, or, rather, how to obtain prints free from the blemish. In the first place, the background and everything except the parrot and cage should be painted out in the negative, so that the background prints white; then, when the impression is printed, the parrot and cage are painted over on the print with gamboge, then a false background must be printed in. When the print is washed for toning the gamboge will be dissolved off, leaving the print intact. Thus a good picture of "Pretty Poll" may yet be obtained. It is by this method that Mr. Edge produced such marvellous results some years ago.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, January 12, 1887, will be *Photographing Snow Scenes*.

ANNUAL DINNERS.—Messrs. W. Watson & Sons, of 313, High Holborn, gave the annual dinner to their *employés* at the Holborn Restaurant on Saturday, January 1, between sixty and seventy being present. Mr. T. P. Watson occupied the chair. After dinner an entertainment, consisting of songs, recitations, &c., was given by members of the staff. The arrangement of the programme, and its rendering by the various performers, merited great praise, and testified to the existence of much talent, vocal and eloquentary, in the firm. The toasts of the various departments and workshops were responded to by the managers. In the course of the evening the Chairman remarked that it was a cause for congratulation, and at the same time a singular coincidence, that, in addition to its being the Queen's Jubilee year, it was the Jubilee year of the firm, having been started in 1837.—On Christmas Eve the *employés* of the firm of Messrs. Bradshaw & Battersby, artists, of Victoria-street, Manchester, held their annual dinner at the "Seven Stars" Hotel. Some good speeches were made, and a most enjoyable evening was spent.

* * * TITLE PAGE and INDEX of Volume for 1886 will be given next week.

GELATINO-CHLORIDE PAPER.

CHAPTER I.

ALTHOUGH for many years past albumenised paper has held almost undisputed sway, there has been latterly a decided tendency to set it on one side and to adopt some other method of printing in its stead. Whether the question of permanency or of mere convenience of production be the exciting cause of the desire for change it is not for us to say, but certainly it can scarcely be set down to any lack of quality of result, for in many minds—especially amongst the general public—an albumen silver print is accepted as the ideal of a photograph. Long years of familiarity with this class of picture have educated us up to that particular standard, and it will no doubt be longer still before albumen paper with all its faults is cast out from amongst us.

Still, there can be no denying the fact that, especially within the past three or four years, there has been a strong reaction in favour of other styles of printing. The enhanced permanency of the platinum print brought that process into use, but for a long time the cold tone was by many considered an objection. Gradually, however, as improvements were made in the process itself and experience gained in its working, the question of tone ceased to be an obstacle to its employment, and as the general taste came to be educated to the new style of image it began to be recognised that the erst objectionable colour was for some subjects preferable to silver, and that the process lent itself readily to the production of highly artistic results.

Next came the various methods of printing by development upon gelatino-bromide or chloride emulsion paper, and these processes, while giving results greatly resembling platinotype prints, possessed the additional advantage that owing to the greater rapidity of their preparation they were available for use with artificial light, and especially for enlarging purposes. Next came the further modifications in development, resulting in the production of pictures resembling in tone the rich colours obtained with albumen, and for a time popular fancy turned once more in the direction of the old familiar style, with the advantage that a few seconds' exposure to daylight, or a minute or two to artificial light, sufficed instead of the sadly prolonged exposures necessary at this time of year with the most rapid albumenised papers.

But it has always been felt and acknowledged, even by the most enthusiastic supporters of the development printing processes, that it is difficult, if not impossible, to secure perfect uniformity of tone in printing large numbers of prints by these methods. Even though the exposures be made automatically by means of specially designed apparatus, and the prints developed in the same solution, considerable variations in

colour are apparent; indeed, we have seen examples where a number of prints made upon a single strip of paper by successive exposures to a steady artificial light and automatically timed, have varied from one end of the strip to the other from almost neutral black to chocolate brown. Where the prints are developed separately the difference is likely to be even greater, though the difficulty seems to lie rather in the paper itself than in the variations of development.

It is, of course, possible in those methods in which toning follows development to do something towards equalising matters, just as in the case of ordinary albumenised paper where slight variations in tone, arising from longer or shorter exposure in the pressure frame, may be modified by the deposition of more or less gold. But this power is limited in the case of developed prints, owing to the greater difficulty in securing desirable tones and controlling the action of the gold bath. Still, whatever means may exist of lessening the want of uniformity, it has been long felt that a process which more closely approached ordinary albumenised paper in its behaviour and results, and which at the same time offered possible advantages in regard to rapidity and permanency, would form a more powerful rival to the old favourite method of printing than any of those we have mentioned.

Within the last few months a process for which such claims are made has been introduced commercially, in the shape of gelatino-chloride paper, for direct printing, that is, for "printing out" without development. Of such paper there are already several brands in the market, but that with which we are most familiar, and which most closely resembles albumen paper, bears the well-known name of Obernetter, of Munich. This, it is claimed, is two or three times as rapid as good albumenised paper, while for permanency it is expected, on theoretical grounds, to be far superior, though, of course, it is too early as yet to speak with any certainty on that point.

No doubt albumen has secured anything but an enviable notoriety in connection with photography on account, as many believe, of the sulphur which forms one of its constituents. Certainly if the want of permanency alleged against albumen prints be traceable to its sulphur, then we must acknowledge that an image formed in a layer of gelatino appears to offer greater chances of permanence owing to the proportion of sulphur it contains (if any) being so much smaller. On the other hand, if we look at the physical characters of the two substances, albumen and gelatine, the latter appears to offer the greatest chance of dangers arising from carelessness or imperfect manipulation. Not only do these dangers lurk in the direction of mere convenience and comfort of working, but also in that of permanency. The

first we may, perhaps, disregard, since if it should eventually be found that the gelatine print is really more permanent, a little extra trouble in its preparation would be but a small price to pay for the advantage. But if there be any circumstances connected with the employment of gelatine for the purpose in question which seem to hold out a chance of danger, it is as well that they should be recognised at the outset, and not allowed to counterbalance any possible advantages.

FOG AND FOGS.

WE dwellers in the Metropolis have an idea that we are in a position to show something entirely unique in matters meteorological. The photographic dwellers in the large towns of the Midlands or the northern counties, or still further north across the Tweed, are forced to submit to loss of business from time to time, sometimes for periods extending over days, but the atmospheric conditions that have already prevailed so long here are *sui generis*. The evil effects of this state of things are not merely local. London, including by the word the outlying suburbs, being the source of the greater part of the enlargements made for photographers throughout the whole country, a complete blight falls for the time over the work of hundreds of provincial studios, for enlarging can scarcely proceed, and artists are literally idle. We so often hear complaints of the latter that it is but fair to show the other side of the question, and to point out that while in many places, north or south, a little dull weather, not anti-photographic, prevails, it is possible for the light, day after day, in town to be such that no painting worthy of the name can be done.

Apart from this local aspect of the peculiarities of this particular season of the year, there is the more general loss to business to be considered. There are few days when outdoor work can be done; but as, with the exception of frost pictures—and the present winter has already offered unusual facilities for this beautiful kind of work—the photographic demand market is practically closed at this time of the year, no one suffers much in consequence. In the studio the very opposite condition of things prevails; the growing distaste for Christmas cards has led to a greatly increased demand for *carte* or cabinet portraits to take their place, and a foggy day or two in the month preceding Christmas Day may make a difference of scores of pounds to some photographers.

This is felt all the more since the attainment of the great rapidity that characterises modern photography practically enables the operator to laugh at dull days. But when a fog invades the precincts of the studio, though the light may be actinic enough, high-class work has been held to be impossible, and the artist is compelled either to lose his client or to send out work that he is ashamed of, as he can scarcely label it upon the back, "This was taken on a foggy day; please excuse."

In some quarters great hopes have been felt that by means of electricity fog particles, after the manner already described in these columns, might be caused to disappear. It is a very pretty laboratory experiment to fill a bell-glass jar with smoke, and then, discharging electricity through it, cause the smoke particles to coalesce into groups and rapidly subside into a layer at the bottom of the jar. Why should not the fog particles behave in the same way? it is argued. In the first place, fog particles are naturally repellent as to their surfaces; they are supposed to consist of small spheres of water, not

vapour, each with a minute coating of a tarry nature, which prevents them running together and forming large drops. Secondly, and this is far more important, the whole experiment so far has been successful as a laboratory experiment only. A year or two ago there was scarcely a scientific periodical published which did not contain glowing accounts of this process having been applied on a manufacturing scale to cause the deposition of the valuable smoke or fumes from the chambers of the lead manufactories, smoke that was highly deleterious in its effects disseminated in the atmosphere, and the exit of which represented the annual waste outflow of so many tons of lead. It is perfectly true that this process has been applied on the manufacturing scale, and we know that large Wimshurst electrical machines of extraordinary power have been "installed" for the purpose. But—this is what has been omitted in all the accounts yet published—no measure of practical success has yet attended the installation. We do not say commercial success will not be ultimately attained, but up to a recent period it very decidedly had not been.

Hence we fear that for the studio no hopes for the present must be built upon the power of electricity to aid. Closing of the doors and windows as much as possible, and keeping up a good heat, night and day, the former especially, are still the sheet anchors of the operator who watches for the departure of the fog so eagerly.

It was not, however, our intention in discussing fog and its effect upon photographs, to close our review by stating that a roaring fire was the only palliative, and that cure there was none, for we have lately been making some most promising experiments of a very practical character. Others may have tried the same, but if so we have not heard of them.

The effect of fog upon photographic operations, to be thoroughly understood, must be viewed in a twofold light. There is first the loss of light caused by the radiation from the sun or the clouds being partially arrested. Granted quick plates and a sufficient exposure, the slowness of action of the light would be the only cause of complaint if there were no other factor to be considered. Unfortunately, however, there is another, the most important, for, secondly, the particles of fog which arrest the more actinic radiations, and so cause the yellowness and consequent slowness of light, likewise reflect the former rays more particularly. Hence the position is this: the fog outside the studio allows only a small quantity of photographically powerful light to arrive at the sitter; the fog inside the studio reflects in all directions, and, consequently, into the lens, so large a quantity of actinic radiations that every part of the plate receives them. The result is a foggy negative, just as though the plate itself had been exposed to a weak light. Let this be clearly understood and our point will be clear. The foggy-ness of the negative obtained when there is fog or mist between sitter and lens is produced by the mist acting as a reflecting radiator of light, and not as a filter or screen. If we prevent the fog radiating light it might be present in large quantity and produce no more harm than if the studio windows wanted cleaning.

In practice this could be effected by having a long tunnel of dark material reaching from the lens to within a short distance of the sitter. The only light received by the fog in the tunnel would be just at its mouth, where its effect would not be perceptible; the only fog affecting the plate would be the foot or two between tunnel and sitter, and it might be ignored.

This suggestion, founded upon experimental trials, must not be confounded with the old "tunnel system" of studio building.

for the light screen we propose would extend well into the illuminated part of such a studio, being brought, indeed, so near to the sitter as just to avoid interference with the lighting it is intended he should receive. If any one will draw a plan of his studio he will find that a tunnel made on this principle, and allowing a full-length view, might be brought up to within two, or, at most, three feet of the figure without casting a shadow, while the distance of a narrower tunnel for half-lengths or vignettes would be reckoned by inches.

In conclusion, we do not hesitate to say that the adoption of such a structure would entirely obviate evil effect on the foggiest day, and when the light was not totally gone many sitters might be taken, and high-class results obtained, when without its aid there must have been loss or the sending out of indifferent workmanship.

Our contemporary *La Nature* has generally some interesting article or paragraph about photography in its weekly pages, and last week its editor (M. Gaston Tissandier) gave a popular account of results already achieved in night photography. Moonlight exposures, as our readers are aware, are no novelty, and this M. Tissandier admits; but the illustrations accompanying his article are of a decidedly advanced character, if they are, or at any rate one of them, is a fair reproduction of the print. It represents a view of the bridges of the Rhône—"facsimile of a photograph taken by moonlight with one hour's exposure." The first moonlight view of the series, taken also in an hour's time, is but indifferent, through the indistinctness of the foliage, owing to the action of the wind. One novelty in connection with it is a white streak suggestive of a huge comet, but which we are informed is the track of the moon during the long exposure, before the expiration of which it had left the field of vision.

If any one desired to obtain anything but a silhouette of trees, with a background of clouds, it is difficult to imagine a more absurd mode of getting a moonlight photograph than one involving that luminary's presence in front of the lens.

THERE is, however, a capital view of a display of fireworks, about which the editor had received so many queries that he obtained from the photographer a description of his mode of working. It was simple in the extreme, and did not by any means involve the presentment of literal truth, "for," says the writer, "the rockets standing out upon a black ground, I had no need for an instantaneous shutter, as I had remarked in photographing the electric spark in an absolutely dark room. All depended upon obtaining a sufficient length of exposure to enable an image to be obtained of a sufficient number of rockets without that number being so great as to cause confusion."

THE radiometer, after a long period of silence, is to the fore again. Years ago, when the marvellous little instrument was first invented by Mr. Crookes, much was expected as to its photographic usefulness; but it was quickly discovered that, for the plates of the day at any rate, its indications could not be relied on for actinometric purposes. The latest idea with regard to it is that the rate of its revolutions might assist the man in charge of the governor at gasworks in deciding when to put on extra pressure as the daylight begins to wane.

THE phosphorescent powder forming the basis of Balmain's paint, the luminous tablet of Warnerke's sensitometer, &c., is known to be in the main a compound of sulphur and calcium, though the exact mode of manufacture is not public property. M. Verneuil has lately given detailed instructions for manufacturing what he terms the most beautifully phosphorescent matter known. The formula runs as follows:—Twenty grammes of lime from the *Hypopus Vulgaris* shell calcined, is pulverised and intimately mixed with six grammes of sulphur and two of starch. To this mixture is added, drop by drop, a solution containing half a gramme of sabintrate of bismuth, one hundred

centimetres of absolute alcohol, and some drops of hydrochloric acid. When most of the alcohol is evaporated, by exposure to the air for half an hour, the mixture is heated in a covered crucible for twenty minutes to a clear cherry heat. After pulverising the mass it is again calcined for a quarter of an hour. If not too strongly heated the product obtained is small grained, lightly agglomerated, and easily crumbled. A new pulverisation is to be avoided as it tends to diminish the phosphorescence. The additions of sulphide of antimony, cadmium, mercury, tin, copper, platinum, &c., produces a variation in the colour of the light which varies from yellow-green to blue-green. Manganese produces an orange tint. Sulphides of cobalt, nickel, iron, and silver diminish the phosphorescence. It is thus seen to be probable that a powder might be devised which should act upon gelatine plates in exactly the same ratio as daylight.

ONE of the dangers attendant upon the looking upon star maps as unerring guides is exemplified in a little discussion that lately was carried on among the Liverpool astronomers. At the annual *soirée* of the Associated Societies of Liverpool, a photograph was exhibited of a portion of the Orion nebula, in which twenty of the stars are represented by lines. The exhibitor considered that the lines were not from stars at all, but from planetoids, and that the lines represent their amount of proper motion during the sixty-seven minutes of exposure. The editor, in a note in the *Journal of the Liverpool Astronomical Society*, looks upon this as a hasty conclusion, and thinks the stars had been allowed to run and that the plate had slipped.

THOSE who were at the lantern meeting of the South London Photographic Society last week, had an excellent opportunity of judging the utility of the electric light for lantern purposes. The lantern and light were under the management of Mr. Davenport, and a brilliantly illuminated screen at the extreme end of the large hall of the Society of Arts, the lantern being at the other end, was maintained without intermission during the whole evening. The arc light was used, and the lamp employed was a Siemens's of what is known as the "focus-keeping" type. The current was taken from a secondary battery charged by a Siemens's dynamo. Of the suitability of electric lighting for the lantern, when working on a large scale and the arc light is used, there cannot be two opinions.

Unfortunately the costs of the plant for the electric light renders it prohibitive for general lantern purposes unless there happens to be an installation on the premises. When this is the case, as it is at the Society of Arts house, all the additional apparatus necessary is the lamp—not a very costly affair. The time will no doubt arrive when secondary batteries will be supplied ready charged, at a much more moderate cost than at present; then, probably, the arc light will be more generally employed when pictures have to be shown on screens of extra large dimensions. Until this time—long promised by electrical enthusiasts—arrives, electricity for the lantern will continue to have a successful rival, both in economy and convenience, in compressed gases.

ON more than one occasion we have directed attention to the effect of the condensation of moisture on negatives, which generally takes place when there is a sudden rise in the temperature in winter. Here is another inconvenience to photographers that often arises through condensation, though the real cause may often be unsuspected, namely, a prolonged exposure in the studio. When the fire is lighted after a very cold night, and the atmosphere becomes warmed, the moisture in the room condenses on the inside of the windows. This moisture is frequently charged with fumes given off from the stove, or with smoke escaping from the flues, which often occurs when the fires are first lighted; consequently in a very short time a thin, yellowish-brown film is formed on the inner surface of the glass. Again, when there is a sudden increase in the temperature out of doors, if the glass be cold, moisture condenses on the outer side. This, especially in large towns, is usually highly charged with smoky matters which form a very non-actinic coating on the glass. These alternate condensations inside and out, quickly form films on

the windows which, although they may not be very conspicuous to the eye, stop out far more actinism than is usually suspected. With orthochromatic plates these non-actinic coatings should cause but little inconvenience.

THE squeegee is a simple tool which, considering its general utility, does not find a place in nearly so many photographic workrooms as it deserves. If a plate of glass or metal, for example, has to be dried a single stroke of this useful appliance will do it in an instant. If a solution or water be spilt on a table or bench it can be more effectually removed by one or two strokes with the squeegee than by a far more lengthy operation with cloths. For quickly removing hyposulphite from large prints, as described last week, it has no equal. Those who make it a practice to have a squeegee always at hand ready for the thousand and one purposes to which it may be applied, are the ones best qualified to speak as to its efficacy.

NOTHING forms a much better lantern screen than a sheet of pure white paper, when the screen is of small dimensions such as those generally used in the drawing-room. A thick and strong paper, well suited to the purpose, is sold by most artists' colourmen. It is known technically as continuous cartridge or drawing paper; it is four feet six or five feet wide, and may be had of any desired length. The price is about eightpence or tenpence per yard for the thickest kind, which is the one that should be employed. A couple of yards of this paper, cemented at one end to a common blind roller and the other to a lath, forms one of the most efficient lantern screens that can be had, while its cost is but a mere bagatelle. When out of use it is rolled up, and then takes but little room, and will be always ready at a moment's notice.

FROM a letter in our "Correspondence" column it will be seen that there is a prospect of an active Photographic Society being speedily formed in the northern portion of our great city. The North London Photographic Association was organized in 1857, and met once a-month for several years in Myddelton Hall, Islington. There were many men of mark connected with it, among these being Charles Woodward, F.R.S., George Shadbolt, J. J. Cole, and others. It eventually died of inanition. About a year ago some gentlemen residing in the northern suburbs were about to resuscitate the Association when they learned that an Amateur Society was then in existence in that district, although of so modest a nature that it was only with difficulty its very existence was discovered. This young Society it is that is to form the nucleus or groundwork upon which is to be erected one of wider scope, and which will be a worthy successor of the once famous North London Association. We commend Mr. Smith's letter to the notice of all North London men.

TEMPERATURE IN THE LABORATORY.

It is but a week or two since we wrote on the subject of the *Lessons of the Frost*, and now we have been visited with a fresh and even more severe attack, the thermometer having sunk as low as 10° Fahr. Under such circumstances it is only to be expected that developing trials have been severe in even the best regulated families or laboratories, though the past week's experience has been sufficient to prove the value of the simple precautions and expedients we suggested in our previous article. Not a single bottle became frozen where those precautions were adopted, and when the tap water was raised to 60° by means of a jug of hot water from the kitchen, development proceeded as rapidly and as comfortably as at any other time. But we gained another experience which was curious, to say the least. Before the frost set in a number of bottles, which had contained emulsion, were placed in a sink of stone in a room used for general cleaning purposes, and filled with water in order to thoroughly soften the gelatine before using hot water. There they remained for three or four days, during which time the temperature

had varied between 50° and 10°. Happening to pass through the room we noticed one of the bottles broken, and at first imagined that "the cat" had been at work, but upon closer examination we found that every bottle was broken—burst, in fact, by the conversion of the contents into solid ice. The surface water had frozen first and so confined the whole, and when the bulk became solid its expansion of course brought about the fracture. These bottles were small ones, holding five ounces. A large, one-gallon glass bottle in the same apartment remained intact, it having frozen only round the sides. Several bottles of solutions of hypo, alum, carbonate of soda and potash, &c., also remained intact, their contents preventing their freezing; not so a bottle of chloride of gold, one grain to the ounce. Its solid contents were not sufficient to prevent its freezing, consequently it had to succumb. Moral, when there is frost about take care that, unless the temperature of the laboratory is kept up, no bottles are left unnecessarily with water in them. Strong or saturated solutions do not matter.

One other circumstance struck us. We mentioned in the articles alluded to the uncertainty that may arise in winter from the practice of employing saturated solutions, showing that what might be a saturated solution in the depth of winter might possibly be less than half the strength of one made in summer. Here is another way in which the temperature may affect a compound solution. Having emptied the developing-room bottle of sulpho-pyrogallol we went to the stock bottle in another room for a fresh supply and found it partly frozen, about one-third of the contents being liquid. Some of this was used to develop a plate, when, as we were prepared to find, the action was extremely slow and the density far greater than we usually obtained with the same plates. The cause was palpable; the liquid portion of the contents of the bottle consisted of a concentrated solution of *pyro*, while the sulphite of soda, originally saturated at a higher temperature, had partially crystallised out, and so the balance of contents was altogether upset.

C. BECKETT LLOYD.

LANTERN MATTERS.

I SHOULD like to say a few words about an experience I have lately had with my modification of the oxyhydrogen jet, as lately described and figured in this JOURNAL and in the ALMANAC. This experience has opened my eyes to a new and very important use for this addition to the jet, and I think I am justified in bringing the matter under the notice of readers who, about this time, are engaged with the optical lantern.

I was asked to give a lecture for a Society whose balance-sheet, at last audit, showed a credit of the not very magnificent sum of 5s. 6d., and it was imperative that I should, as much as possible, keep down expenses. To employ my usual operator would have entailed a disbursement of several guineas, so I resolved to trust to my own jet and an "operator" who had never seen the limelight before. This may seem, to experienced lanternists, rather a risky experiment, but "all's well that ends well," and this is how I managed. Before the audience came in at all I turned my tap full on, got up the best light possible, centred and focussed the disc, and so was quite ready to start. But, having no superfluity of hydrogen, I did not want to burn even the small jet of my bye-pass, so I left the "normal" taps just as they were when the light was at its best, turned down my own taps, and cut the gases off at the bags. Just before going on to the platform I turned on the bag taps, lighted the small hydrogen jet passed by my bye-pass, and when I gave the signal to my operator he simply turned my tap full on, and we had a splendid light which never was touched till my half-time interval, when I turned on a little more oxygen as I found the flame a shade too red. The light remained splendid without interference to the end of the lecture.

I was using for the first time a jet (mixing) made by Mr. Newton, of Fleet-street. The nozzle of this jet is less bent than any I had ever before used, and I found, as I expected, a vast improvement in the light arising from this circumstance. So far as I can by experience determine the incandescence area for showing slides on a screen should not be too small, not altogether a "point." When a somewhat large area of lime is covered, I think the illumination is more even, and I am sure the lime does not "pit" so much. I do not

like the "pitting" of the lime, it is dangerous for the condenser, and I fancy the light is not quite so good. With other jets, where the nozzles are considerably bent and the flame impinges at a smaller angle on the lime (that is, strikes it more "straight on"), I have found deep "pits" in the lime, and the lime almost invariably has split after a short time. On the last occasion, with the straighter nozzle and the more obtuse angle, the lime was not really "pitted," and did not split at all either during or after the lecture; it would do again if required.

I have only two or three times used the limelight for micro-work, but in these few cases I have found a "point" of light better than a larger "area," and there was no condenser in any danger. But for screen work I am inclined to favour a pretty straight nozzle and a fair area of incandescence.

ANDREW PRINGLE.

WHAT IS AN AMATEUR?

ONE of the latest contributions towards the solution of the vexed question, What is an amateur? is Mr. Adcock's able and thoughtful paper read before the Camera Club, in which he discusses at some length the motives which first of all induce to the adoption of a hobby, and afterwards the lines upon which that hobby should be ridden. Starting upon the broad basis that an amateur is one who follows some particular pursuit as a means of profitably filling up what would otherwise be waste time, the writer shows how the nature of the selected pursuit may vary according to the circumstances of the individual, and that what may in one instance be downright hard labour is perhaps in another healthy recreation.

But it follows naturally that the chosen hobby should be one to which the amateur is naturally attracted, that, in fact, the element of love should step in, otherwise the very term amateur is a misnomer. This condition fulfilled, we have the true amateur. But this does not even touch the vexed question of the day, "What constitutes an amateur for exhibition purposes?" Here we have entirely new conditions introduced, and it is the disagreement on these points, well exemplified in the discussion which followed the paper, that constitutes the bone of contention. Mr. Gifford insisted that an amateur should prepare his own plates in order that all might be on terms of equality, while the author of the paper, as well as Mr. Rodgers, held that the art aspect of photography should be the more prominent. As another speaker, Mr. Farrell, pointed out, each side is no doubt right from its own point of view, the decision depending entirely upon individual idiosyncrasy; the amateur with a leaning towards the chemical side of photography will attach the greater importance to and derive the greater pleasure from that portion of his work, while he of an artistic turn will view that portion of his labour as merely the means to an end. Consequently so long as the vicious distinction between amateur and professional exists at our exhibitions, so long will the divergence of opinion continue.

After all, the distinction, so far at least as it affects exhibitors, is but a modern one. It is but a brief period since the custom of offering prizes for amateurs only was instituted, and then simultaneously dropped the question of status. Let us, then, drop the custom, and with it the uncertainty as to who are and who are not entitled to compete as amateurs; for obviously, if justice is to be done all round, it will be necessary, as suggested by Mr. Farrell, to establish a series of grades, varying from the amateur who regards the *technique* as the all in all, to the one whose contribution to that branch commences and ends with the removal and replacement of the cap of the lens.

This, after all, is only a distinction between amateurs themselves, with a view of placing all upon equal terms, but there still remains the classification of amateur and professional. I see less reason still to perpetuate this distinction, for the mere fact of a man making his daily bread by photography scarcely tends to cultivate his artistic perceptions to any higher point than he would be competent to attain as an amateur. Nor does his constant application to photography as a business lend him any great assistance in the production of pictures suitable for exhibition. These are not found, as a rule, among the everyday productions of the commercial portraitist, or landscapist either for that matter, who in order to become a successful exhibitor must devote a considerable amount of time and thought to unremunerative work, and who in fact, for the time, assumes the rôle of amateur.

The amateur, on the other hand, labours under no disadvantage on account of the bulk of his energies being devoted to some business or profession other than photography. The fact of his having embarked in the pursuit indicates a predisposition in its favour, and even if the time actually devoted to his hobby be limited to the utmost, he will, when so engaged, bring to bear upon his work an amount of energy and freshness of mind scarcely to be expected from the professional, jaded as he must be with the mechanical drudgery of his daily task. Less still need those happy individuals complain whose time and resources are devoted unrestrictedly to the practice of the art. Let us then sink all distinctions and throw every competition open to all comers. Let those who feel themselves incompetent to take part in the struggle without being handicapped or classed, wait until, by dint of work and study, the race seems open to them; and I venture to say that our exhibitions are not likely to deteriorate either in quality nor quantity of matter.

With regard to the subject matter of Mr. Adcock's discourse, when I come to the "What?" I cannot help thinking that the author sets a somewhat difficult task to his hearers and readers. I know it is a good precept to "aim high," but in practice it may lead to disappointment and failure. It is not every amateur, whatever may be his artistic attainments, who is in a position to devote sufficient time to the "study of figure" to score success. Models are difficult to find, and still more difficult to imbue with the feeling the artist intends to convey; and, though a successful figure study is of all artistic efforts the most valuable, there is no branch in which photography fails so miserably when it only reaches mediocrity. Mr. Adcock himself has made his mark in this line, but I fear not one in ten even with his energy and training and devotion to the pursuit, would have been so successful, while I am quite sure not one in a hundred of the rank and file of amateur photography have the time, means, or resources that are necessary to ensure even a moderate degree of success.

Just one other point in the paper I would touch upon briefly. Mr. Adcock says:—"Refuse to give prints except in special cases," but, he goes on to say, find a small photographer and give him the printing to do at a fixed charge, and make your friends pay. This, I submit, is straining the "amateur" question too far. It may or may not be a question whether an amateur ceases to be such if he charges his friends cost (or any other) price for their pictures, but I take it to be a different question altogether, and a decided injustice, if he is to be debarred from giving away prints. In the first place, no injustice is done to professionals—that is what Mr. Adcock desires to guard against, and it is a most laudable object—for in ninety-nine cases out of a hundred the sitters of an amateur are pressed into service and made use of by him for his own sake—the sake of practice—and they would never have thought of going to a professional to be photographed. But setting that on one side, most amateurs worth the name would prefer to lavish a little more care on the production of their own prints for friends than would be likely to be given to them by a "man with a small business" who is to charge a "fixed and not high price." The description of the workman, and the conditions under which he is to work, do not suggest a high class of probable result, while I am afraid if he were in a larger way of business he would either refuse the job or charge a sufficiently high price to pay him for the inconvenience of going out of his ordinary way. Photographers, as a rule, do not care to execute any more printing than is required to supply their own clients; such is my experience. If they have not much printing of their own to do, perhaps their work is not of the best.

If the amateur, instead of being allowed to freely give his prints to friends, is forced to choose between the course suggested or making a charge himself, I am afraid the result will be that his negatives would soon be of little value to him, and gradually he would cease to take the trouble to produce them. But such a restriction is quite unnecessary.

H. Y. E. COTESWORTH.

ORTHOCHROMATIC PHOTOGRAPHY.

[A Communication to the London and Provincial Photographic Association.]

ORTHOCHROMATIC photography, although not new, is at the present time receiving a large amount of attention both by dry plate makers and photographers. It is a curious fact that a discovery to render

the yellows lighter than the blues was not taken up with more zeal at the time of its discovery, and that it should have laid semi-dormant for some years until a commercial firm takes to supplying the public, which starts it into life again. I am referring only to England, as on the Continent they have employed it for some years, but we English are always somewhat behindhand in taking up a new discovery.

I am not going to discuss who is the legitimate claimant of producing orthochromatic effect in photography; but it is my intention this evening to give you the results of my experiments as far as I have gone (there is nothing original in the chemical I employ, it being erythrosin, and that was discovered years back), and to place in your hands a really good orthochromatic formula, but with one drawback, they will not keep many days.

The formulae which have been published compounded with eosine and ammonia, into which dry plates are to be dipped, have in my hands proved useless, and I believe others have found the same. One of my experiments shows me that chloride of silver dissolved in ammonia with eosine and used as a bath gives orthochromatic effect, and I should imagine that if a plate is made containing chloride of silver and then bathed in a solution of ammonia and eosine it ought to answer; probably this may account for the failures of those using the ammonia eosine bath with ordinary plates. After various experiments with different compounds with eosine or erythrosin, I found that carbonate of silver dissolved in excess of carbonate of ammonia and mixed with the erythrosin gave me the best effect.

The orthochromatic effect in a plate is due not to eosine or any other stain being an optical sensitiser, as some state, because you may stain the film as much as you please still the yellows will refuse to impress themselves upon the film, but I believe it is due more to a chemical change which is produced by having free silver present as well as a new compound formed with the erythrosin.

Although I discovered the above (*i.e.*, the use of silver carbonate with eosine) quite independent of anything that had been published, I see that I have been somewhat forestalled in the publication of the formula, as last week in the *News* appeared a formula with ammonia, silver, and eosine, by Vogel, and, I think, the week previous another formula containing fluoride of silver, carbonate of ammonia, and eosine, which practically amounts to the same as I have given above. Mr. Hastings will bear me out in what I say, as I confided my formula to him some four or five weeks ago. However, I need hardly trouble you with all this.

After trying various proportions, I find the following to work fairly well:—

Silver nitrate	20 grains.
Ammonium carbonate	90 "
Water, distilled	16 ounces.
Erythrosin (2:1000)	10 drachms.

The plates are placed in this for two minutes. A rinse in distilled water gives less chance of stains, and then placed in a rack to dry. Let me here state that if they are used in the moist condition the orthochromatic effect is practically *null*: they must be used quite dry. By this treatment the plate is rendered three times more sensitive.

I must insist upon the necessity of using only ruby light, the plates having now become so sensitive to yellow that the greatest precaution must be taken in handling them.

My chief reason in not giving you this formula before was the great difficulty of developing the plates free from fog; this I am glad to say I have now overcome. I pass round a plate half of which is quite free from fog. This was got rid of by soaking the exposed plate before developing in the following:—

Potassium bromide	120 grains.
Ammonia	$\frac{1}{2}$ ounce.
Water	10 ounces.

Do not allow to remain more than thirty seconds, well rinse under the tap, and proceed to develop with any of the usual developers—ammonia, potash, or ferrous oxalate.

If there is much blue in the object to be copied, a yellow screen must be used if exposure is to be made by daylight, although by gas or lamplight it is quite unnecessary. The best effect is always secured by gaslight exposure.

A very good substitute for coloured glass is to colour a collodion film and strip it from glass. The glass should be rubbed over with tale or a solution of wax in ether, and well polished off, and coated with collodion containing methyl orange. The dried film should appear decidedly orange. The stripped film can then be gummed to the cap of the lens, having cut out the centre first, and used preferably behind the lens.

The carbonate of silver and erythrosin may be mixed with an emul-

sion, but requires great care. It should be mixed at as low a temperature as possible, and the plates used as soon as dry, as their life is very short. The orthochromatic effect is very marked, and the speed increased about ten times. If any one is desirous of trying this I give the following:—

Emulsion (containing, say, 200 grains silver)	10 ounces.
Silver nitrate	10 grains.
Ammonium carbonate	45 "
Erythrosin (2:1000)	5 drachms.

Before development they must be treated with the ammonia and bromide.

Very fine results can be obtained from collodion emulsion, in fact, the results far surpass gelatine, and can be used by daylight without the necessity of employing a yellow screen at all, but, alas! like gelatine, do not appear to keep any better.

The bath for a collodion emulsion plate is best made as follows:—

Silver nitrate	10 grains.
Ammonium carbonate	45 "
Water	2 drachms.
Spirit, methylated	8 ounces.
Erythrosin (2:1000)	5 drachms.

Dissolve the silver in a test-tube by heat in two drachms water, and add the carbonate of ammonia bit by bit till all dissolved. Add the spirit gradually to the hot solution, and finally the erythrosin. Place the dried collodion plate in this solution for two minutes and dry; the plate before development to be treated with the ammonia and bromide, and developed by ferrous oxalate, three to one, to each ounce of which add three grains of bromide.

If mixed with the emulsion it begins to fog at the end of three days, so it is better to dip the plates as required. The exposure is only four times more than a fairly ordinary rapid gelatine plate by daylight, and by gaslight they are about equal.

The action of the erythrosin silver compound renders the collodion film exceedingly tough, very much like an alumed gelatine film, and is very difficult to scrub off the glass afterwards.

I must now leave you to try for yourselves all I have stated, and trust some of our members will make further experiments to produce something better and more lasting than what I have done.

J. B. B. WELLINGTON.

ON THE PRODUCTION OF TRANSPARENCIES FOR THE OPTICAL LANTERN BY THE WOODBURY PROCESS.

[Abstract of Communication to the Photographic Society of Great Britain.]

THE specimens of artistic photography, as I venture to call them, which I shall show you this evening, are so called because they are absolutely untouched. They will include some of the most commonplace objects and grimy scenes, and owe all their artistic value not so much to the beauty of the object as to the selection of point of view and the accurate rendering of the light and shade. If therefore they appear to stand out in stereoscopic relief upon the screen it is only because the light and shade are accurately rendered. This alone confers upon them the right to be considered artistic; and, being done by pure photography, seems to me to be incontrovertible evidence that photography may reach the position of a true art. The greater number of course will be microscopic subjects, the extraordinary beauty of which is, primarily, entirely due to the great skill of Mr. Evans in this particular branch. But I shall show a few others to emphasise the principle involved in their production.

I will return to this part of the subject later on, and proceed at once to the method of printing. It is hardly necessary to describe the Woodbury process to this Society. The usual pellicle of gelatine made sensitive with bichromate of potash was exposed to light behind each negative; the soluble gelatine unacted on by light washed away; the remaining insoluble *relief* pressed, by hydraulic pressure, into the lead forming the *mould*, from which the casts, or prints, in a pigmented solution of gelatine, are in fact the slides before you.

As however the permanence of all photographic pictures is important, it is necessary that I should say a few words as to the probability of their permanence. I produce one which was exposed to light for many years in a show frame; the red all faded out of it long ago, but the black remains. It was also exposed to great extremes of moisture from the every-night condensation on the window, the paper binding having completely perished from that cause; but the gelatine film is uninjured, though unprotected except by the cover-glass. I was however quite prepared to hear that fungi attacked the unprotected film in Burmah, for I have seen many such in this country. It will therefore perhaps interest you to

know that a coating of plain collodion will not only protect the slide from any such attack, but go a long way towards the perfect restoration of those already badly diseased, leaving hardly any visible trace. As a matter of fact, also, every slide that I have issued since 1879, when the business came into my hands, has been so, or similarly, treated. I may as well mention here that I have found this same plain collodion the best of all varnishes for gelatine negatives, its tenacity being remarkable when of the suitable horny kind. The negative I produce so protected was left out of doors and forgotten during the many winter months of the winter 1884-5, with the bichromated gelatine too, in one of the commonest of printing frames, buried in the snow for days together, and is practically uninjured.

Still I have not trusted alone to varnishing. For the last two years all my slides have been provided with a gelatine which would appear to be practically imperishable, the addition of bichloride of mercury completely protecting it; at any rate, under the more unfavourable condition of being swollen with moisture, from all mildew or other signs of decomposition. The only pigment employed is pure lamp-black collected from the tip of a benzoline flame, which gives the superb brown you now see.

Mr. Evans will tell you of the happy chance which resulted in our meeting, but he probably will not tell you what our real difficulties were in carrying out his projects, or how we surmounted them. The object in view was to secure photographs which should be faithful reproductions of what he saw in the microscope. This necessitates the greatest nicety of illumination, of which you must allow he has shown himself a master. It necessitated the use of the ordinary microscope appliances, and the photographing of the objects through the eye-piece, and consequently a great variety of objections. Subjected to this crucial test, their performances varied sufficiently to cause some difference in the value of the results, but it was decided to go on, aiming at pictorial quality rather than microscopic definition.

The principal difficulty however was in obtaining negatives suitable for my purposes, for I am pleased to see that it is at last recognised that process has a good deal to do with the type of negative that should be considered good. What is generally considered as a fair-printing negative is my ideal of the worst possible type, namely, one that is many times over exposed, and supposed to have been saved by development. We gave that an exhaustive trial, having full faith in bromide and ammonia, combined with brains. But our brains failed us utterly here, and would have abandoned us altogether if we had not abandoned bromide and ammonia for a fairly reliable normal developer, and been guided by exposure alone.

A distinctly acid, fully saturated ferrous-oxalate developer is the most powerful and rapid developer I am acquainted with, too rapid for comfort in most cases, yet with it to obtain a perfect negative of one subject may require prolonged development, while another to be equally perfect would be developed in less than a minute. I illustrate this by producing one of Mr. Evans's earlier negatives, which, being far too feeble for my purpose, I took the trouble to reproduce. The positive was made on one of Ramsden's slow bromide plates, made specially for me for the purpose, without exposure to light during manufacture, and the one now shown was the result of one second's exposure to a lamp flame, and six hours' development in the strongest ferrous oxalate developer many times renewed. I was so fascinated with this that I reproduced many more, every succeeding exposure proving more and more fully that exposure is everything, developer quite secondary.

I cannot imagine why the ferrous-oxalate developer has fallen into disfavour; the latitude of exposure is enormous if only a fair printing negative is desired. Its effects may be summed up thus:—Less than one unite of exposure will give an under-exposed negative utterly useless for any process. One unite of exposure will give an ideally perfect negative, clear glass in the deepest shadows, but may require very prolonged development with the strongest solutions possible. Two units of exposure will give a brilliant negative suitable for platinotype, developing usually in three or four minutes. Four units of exposure will give a good silver printing negative, developing in less than a minute.

The time occupied in development depends necessarily very much upon the degrees of contrast in the subject. These remarks therefore apply primarily and more particularly to those of no undue extremes of light and shade; in a word, to those subjects which photography is capable of rendering artistically in monochrome. Cases, however, occur which present more than ordinary difficulty in microscopic objects, for instance, preparations of insects of a dense non-actinic brown, as the thorax, while the wings are almost perfectly translucent. In ordinary everyday photography an analogous case

is presented by a distant snow-clad range of mountains with dark near foreground. In these cases a very prolonged exposure is necessary in order to preserve luminosity in the deep shadows, but accuracy of exposure is only the more essential, and then a well-watered developer—or, more simply, a nearly-exhausted developer—will secure the desired result.

I do not think that many photographers whose experience has been confined to silver printing alone, are capable of judging what qualities in a negative are necessary for other processes. For my own purpose I prefer the minimum exposure allowable—that is, the ideally perfect positive collodion picture on glass, developed or otherwise brought up to printing density, a type of negative in vogue on the continent some fourteen years ago for silver printing by Angerer, of Vienna.

Of course, we all know that albumenised paper presents extraordinary facilities in the hands of expert printers for obtaining good results from very different classes of negatives. It is, in my opinion, a dangerous property, and one that has done much to retard progress from the want of a definite standard of quality in negatives.

But I am wandering from my subject, which is the Woodbury process. Here I am at home, for I have found in it a process which will do all I require without retouching, if the negatives are right.

Mr. Evans will confirm my statement that if a negative retouched in any way comes to me the first thing I do is to remove the retouching completely. But I willingly confess that I sometimes retouch extensively, but it is entirely limited to the inevitable process known as spotting, for which the Woodbury process offers facilities which are simply irresistible. Plates of commercial makes do sometimes have slight pinholes or opaque spots. Microscopic objects abound with dirt specks in the mounting. All these are remorselessly cut away, as they are developed as projections easily removed either on the gelatine relief or the metal mould. But I have not yet dared to meddle with the modelling that nature does, for the simple reason that with the gentlest guidance she will do it for me.

GEORGE SMITH.

CAN PHOTOGRAPHY LIE?

[A Communication to the London and Provincial Photographic Association.]

I WILL try to analyse and see whether our beautiful art-science can be put to such base use. I have an abhorrence for untruth, and hope to meet with your forbearance when I presume to occupy your time in a discourse to which I feel myself little able to do justice; I am nevertheless assured that you will excuse my shortcomings, and with this encouragement will try to expose the culprit, and, if I can, will endeavour to find an excuse for his shortcomings. Although entailing several digressions, I will adopt the easiest and most familiar way, and go through the operations with the geni of science to whom I have the honour to address myself.

My professional day breaks, but not my fast, therefore must do both to nerve myself for my exertions. Scarcely have I given my mind to this important *initium* when I am bothered, no, honoured, I should say, with a gentleman whose duties in the City lay upon him the additional obligation to choose such an inconvenient hour for the laudable gratification of his desire to perpetuate his present appearance through my humble instrumentality. He enters with such airs as seem to be required for the occasion, makes the usual remarks about the suitability of the weather, informs me in the same breath that he can only grant me five minutes of his presence, tries to bind me down to finish a proof same day, and, this being found impossible, asks the earliest opportunity when I shall be able to do so; and three days hence being mentioned as the earliest possible date, informs me solemnly that that very evening being the time when he leaves town for a considerable period, hopes that he should not be disappointed, and, requesting me politely to make haste, follows me into the studio. He only wants a bust, but is not quite sure whether his legs should be appended thereto, but, yielding to my suggestion as to the impracticability of such a pose, leaves it entirely to me, which somewhat restores my hopes of settling a dispute with my inner man, who seems somewhat unreasonable just now. Alas for human expectations! My sitter has altered his mind now, and wants a cabinet. Having exchanged plates I emerge once more from my dark room, my inner man revolting all the while, but, suppressing the voice of the deep, effectually succeed in composing myself, the picture, and the man, who, not being very partial to the head-rest, indulges in strong epithets upon that already much-abused instrument. However, with heroic effort I adjust, persuading him to grin and bear it. He objects to the one and submits to the other, and while he is listening to my sudden, incoherent talk, in which I make a desperate effort to count seconds at the same time, the trick is done (thanks to my pneumatic shutter), he protesting that he has moved, while I give him the contrary assurance. The young lady not having arrived yet I cannot hand him over to her persuasive talent, so, on his hurried preparation to vanish, I have to leave development to handle the pen instead.

"Good morning! Afraid shall lose my train! Send the proof on."

"Beg pardon, but it is our rule to pay at time of sitting."

"Oh, must I pay a deposit?"

"No-o, that is not necessary; but to save booking, confusion, &c., we prefer the whole amount."

"I leave my card. I have never before paid anywhere. I am a friend of the Lord Mayor's footman. You can inquire. It is monstrous! It is —"

However, on my calm insisting upon payment, and finding no more answers to my arguments, he disburdens his conscience, and thinks having to pay once he may as well do it now. I think so too, and hastening back to my coffee I hope to get an opportunity to study my next sitter a little more in order to accomplish my task of detecting the liar. Now, liars are not very candid, so I have to be vigilant. That I myself should have been guilty of that for which others are called to account by me matters little, for, according to ancient usage, it is not at all necessary to see the beam in one's own eye, but it is very desirable to expose the mote in the other. Now for another cup of coffee; another lump of sugar wanted. Whether it is coincidence or sarcasm, my wife responds with an assumed substitute in the shape of a fair lady sitter, who, if she is innocently unaware of her sweetness, must be convinced of being a lump, for how could she be deaf to the greenings of my newly mended posing chair! Exquisite subject, though, for my contemplation. This time the sitter is introduced to me in the stronghold of my labours, the studio, by my young lady assistant, who has the audacity to expand her arms insinuatingly in apparent imitation of the arithmetical rules of bulk. I have some difficulty in preserving my dignity and administering a visionary rebuke, which is, however, totally lost to the intended recipient by the interposing object of my operations. I bow politely, explaining away the lady's fears that she never makes a good photograph, beg of her to be at her ease, in which kindly meant suggestion I miss the mark, however, for, it being hot, she looks at me in astonishment, and, through the combined use of fan and handkerchief, leaves it not uncertain that she wants to convey to me that ease is out of question. An additional headache is not considered a deterring circumstance, inasmuch as I am informed that the photograph has to be finished by her husband's birthday, which happy event would occur within three days, and, if it did not give entire satisfaction, I would of course give another sitting free of charge, finishing up with the earnest request to be represented in such a manner as not to exaggerate her form, which, though it could not be called thin, was decidedly not of such dimensions as would account for the extraordinary size by which she had been misrepresented by previous photographs. What a splendid chance for the embellishment of my subject!

"Head and shoulders? Yes, madam. Pray stand there."

"I hope you will not keep me long standing. Can I not sit?"

"No, madam. If I am to rightly represent your features" (I had nearly blundered out, "reduce your features") "you must kindly stand. Turn a little, please. No, no; I want to show the front. You will excuse, but a slight turn imparts grace, when such is naturally present."

At this juncture I carry my point, and having introduced a longer focus lens into the camera proceed to focus. If any little delay is occasioned by the changing of the lens, it is always advisable to display either all the scientific knowledge you possess, or so much of it as will suffice to fill up the interval. By so doing I nearly forget to take cognisance that my fair sitter's hair, in colour, represented the very lowest strata of the spectrum, which fact obliges me to use a plentiful supply of powder. After having thus isochronised my subject, I draw most of my curtains to ensure the necessary reducing effect, which, to some little extent, a well arranged set of curtains can do if they have not been shifted too much or too little, give a full exposure, and, at the sitter's request, a glass of water and *Punch* (I mean, of course, the comic serial) to the sitter, and repair to my dark room, which, through the introduction of a single sheet of canary medium in place of the deep ruby red, has lost many of its horrors. I proceed to remove a burnt sienna backing (which, by the way, I procure from the nearest oil and colour shop, and apply to all my plates) by passing one hand to and fro under the plate, which I hold with the other under a stream of water; this proceeding has the additional advantage of soaking my plates. I then apply a developer,* which consists of the smallest quantity of pyro compatible with density, and of the highest permissible allowance of ammonia .880, restrained with such minimum of bromide as will just prevent fogging. By this means I find out with tolerable certainty whether the exposure was correct shortly after immersing, and before it is too late to apply more of the restrainer, the immediate addition of which I think advisable in every case, when, upon the application of the developer, it becomes evident that the plate has not been under exposed. When the first indication does not afford me sufficient clue as to the correctness of the exposure, I examine quickly by transmitted non-actinic light, which then, from the greater or lesser density, constitutes a sure guide. When I know or find my plate to be under exposed I reject it at once; but in the exceptional case of not being able to take another negative, and suspecting under exposure, I flood the negative first with a weak, unrestrained, ammonia solution,

* Since writing the above I have become a convert to the potash developer for some plates, and soda developer for others.

and then apply the normal developer. By the help of artificial light (which, for dark-room illumination, I hold to be a *sine quâ non*) I am well able to control the density of my negatives to such an extent as to make the use of the intensifier an exception. Should I have to resort to one, I have a partiality to the one recommended by Monckhoven. As far as my own observations go this method seems to be permanent. I now rinse my negative, pass quickly through a salt bath to arrest osmotic action, wash well in a syphon—which holds my plates perpendicularly—fix in sodium thiosulphate (I scorn hyposulphite), wash well in a syphon, and dry my plates on pegs driven into the wall very near the ceiling, just over the kitchen fire, or, if necessary, hasten this process by repeatedly flooding with methylated spirit.

Do not however imagine, Mr. Chairman and gentlemen, that I am so much wanting in courtesy as to keep my sitter waiting while I thus ruminate. No, no, even if my lively imagination had tempted me to that it would have been of little avail, for before I have time to finish, tap, tap, tap, on my dark room door, a voice, "Is the focus a success?"

To which astounding display of amateur knowledge I can only faintly retort, "Yes, the focus is," and I added inaudibly, "but the focal length might have been still greater."

Examining the negative, however, I have cause to congratulate myself, for so far I beheld the negative counterfeit of my fair sitter in such an aspect as only three years' exercise in a lady's modern drill class, aided by Madame Rachel, could possibly impart. My thoughts fly to the still more beautifying process of retouching, and overfilled with joyous anticipation of the resulting portrait, and noxious fumes nearly bursting—the door open, I announce that the result is all that could be desired.

The lady's gracious parting remarks that if the portrait should please her she would recommend countless numbers of her lady friends whose focus coincided somewhat with her own, brought me back to my subject, and I began to wonder whether it was right to pencil an untruth to please a customer. I answered the question to my satisfaction in a very convenient way. I reasoned, firstly, that if a photographer placed a photographic instrument before a very stent sitter and took a negative copy therefrom without more ado, he should in all probability exaggerate his subject; that would be a lie of necessity, but also would undoubtedly be a financial failure if indulged in to a considerable extent: this failure would be inexcusable in the eyes of the world. If, on the other hand, with the aid of pesing, lighting, swing back, long focus lens, and retouching, he could produce the other extreme, and did so, he would still be a liar, but his lie would be an excusable one, and, furthermore, would not be attended with commercial failure. But here the artist painter steps in, dictating to keep the truth, and the following dialogue is suggested to my imagination.

Photographer. So you would have me portray my sitter's individuality—faithfully represent character, not even minimise the stoutest form?

Artist. Yes, that only is true art.

P. Pray, sir, what would you do if your sitter dressed her hair in a totally different fashion to what she usually wears it, and twists and turns her mouth until all individuality is gone?

A. I should most assuredly suggest an alteration, and paint naturally from observation.

P. I could not do that, because I should not find it out until the portrait is finished. You may alter *ad libitum*. Your paint does not cost much, and you get £20 for your work; I get £1, and every alteration entails an outlay of several shillings. Moreover, you require several sittings; I have to do the work in one. You converse, conceive, and idealise, and perpetuate at once; I may converse, and conceive the ideal, but only wish that I may get it.

A. But, my dear sir, the instantaneous process.

P. Much of that is an exaggeration, as I think I can prove some of your work to be.

A. Do not add insult to injury.

P. I have no intention of doing so, but I can prove to you that you do not represent your subject truly at all times.

A. That is impossible. I study the character of my sitter, give a natural pose, light my subject well, foreshorten where necessary, and there you are!

P. Now if your subject is such as would be quite unrepresentable in the truly natural state?

A. Oh, then I moderate it just a trifle to make it acceptable, you know!

P. I have caught you now. By your own words you prove, in a simple manner, what I meant to prove more elaborately. You have saved me that trouble.

A. Oh, you incorrigible! I will give you a little of my mind. I could never see that a photographer should be entitled to use the name "artist."

P. Well, I will explain that. An artist, with all the qualities inherent which make him so, will still have to learn the mechanical part of using brush and colour; he conceives the idea, he composes his subject, he idealises it, distributes lights and shades, and reproduces the whole on canvas.

A. Now, what does the artist photographer do?

P. Why, up to the mechanical reproduction, he does the very same thing.

A. Well, my good friend, what happens then?

P. Why, then the photographer bears off the palm, for his genius has

a still further task to accomplish. Every study or subject which has to be conjured up in thought only by the artist, will have to be produced and brought face to face with the camera, and very often needs training; and then, O! then, if the photographic paint would but take kindly to the paper! Alas, how much canvas—in the shape of dry plates—is spoiled before success rewards the effort!

But enough of this. It is time to recall my thoughts from imagination's flight, or I fear my patient hearers will wish me to use my wings until I am happily out of sight.

Speaking-tube whistle: "Baby cabinet; be sure you get a good one. Lady says that you have a reputation for babies."

Though this is rather an undefined compliment, I feel nevertheless flattered, and consequently cannot very well refuse to please the mother by fulfilling her desire to make it appear as fine and large a child as possible. Oh, dear! As far as I am able to judge through the speaking-tube, the dear's consent has not been obtained. All doubts on the matter are completely removed when the dear, on its way to the studio, propelled by the mother and dragged by the nurse, insists upon indulging in the process of voice strengthening to an extraordinary degree. I meet it with a toy, but in return am met with a slap in the face. However, I am not disabled, so lend my whiskers to inspire confidence. Unfortunately, I have to retreat, but remembering that my reputation might be somewhat at stake, I determined to hasten matters by the suggestion to hoist the dear upon a chair. That being impossible, I try in succession swing, balustrade, pedestal, tricycle, table, and then the floor. This proved to be the safest ground to work upon, for the darling rolled itself into a laughing fit, when, with the help of a doll, a trumpet, a musical box, and a bell, I actually succeed in focussing the little prince, as his mother called him. Little prince, indeed! His only princely qualities appeared to be the way in which he ordered everybody about. I call him a despot.

There, now; here was a chance. Dear! dear!

"Madam, you must kindly leave it entirely to me. You spoiled it."

"But I must see the darling's legs."

I saw that too, so I tried again, when, in consequence of the too close proximity of the mother, I obtained too many legs that time. I got six, the baby's in duplicate, and the mother's as well. My efforts to induce the little tyrant to take possession of the posing chair were more successful this time, the mother proudly watching this offspring of affectionate nature's pranks, sitting by its side, a veritable illustration of maternal pride.

Here is the picture, Mr. Chairman and gentlemen. I value it because it constantly reminds me of the lesson it conveyed when I committed the indiscretion to show the negative. With the mother's sudden exclamation that it only wanted Punch the other side, it dropped, accidentally or purposely I know not, but that only was saved. As it was the best expression baby was capable of exhibiting in its present state of existence, it was agreed to print a vignette copy from the savings. Receiving intimation that Mr. Spark, who brought an electrical apparatus to be photographed, could stay no longer, I had to hasten matters. As the negative of the baby had purposely been taken with a C.-D.-V. lens, and consequently made it appear a bigger child, I had no difficulty to persuade the mother to accept it, and bidding adieu with a secret good riddance, I prepared for the electrical spark—I mean Mr. Spark—who brought the instrument. It was made entirely of brass, of a deep yellow colour, with blue handle and foot. It occurred to me to use an azaline plate. I placed a yellow glass medium behind my lens, but could not obtain a sharp image. I therefore hit upon the plan to pour colour-stained collodion over the back combination of my lens, which had the desired effect. For experiment's sake, I then exposed an ordinary gelatine plate through the yellow medium on the same object. It proved to be almost identical with the azaline plate. Subsequent comparisons with stained and unstained plates gave me similar results. Whether it had been forgotten to stain the plates, or whether the stain that rested upon them was, that they were only imperceptibly more sensitive to the yellow rays, I will not presume to say. I shall try Mr. Ives's process next.

(To be continued.)

J. HUBERT.

Department for Inexperienced Photographers.

HOW TO MAKE A NEGATIVE.

WE shall at present dismiss all considerations respecting a camera and stand (concerning which we shall have a good deal to say in subsequent articles), and shall take for granted that these are already in the possession of the young photographic aspirant in whose interests we are now writing, but who does not as yet quite clearly know how he is to proceed to work.

Having mounted the camera on the stand, let it be pointed towards some out-of-doors subject on which there is well marked light and shade. This may be a brick wall in a garden or a house at no great distance, by preference one on which the sun is shining obliquely at the time. Should any "sisters, cousins, or aunts" happen to be in the scene no special harm will arise, only as the first trial may not be all that is

desired it is wise to operate under such circumstances as to prevent unpleasant inquiries being made, just at first, as to the measure of success, and to bury one's sorrows in secret.

Rack the lens or camera in or out until the image is seen clearly depicted upon the ground-glass—the focussing screen—of the camera. Here note that the focussing screen has a two-fold use: it serves the purpose of composition by enabling the operator to see precisely the nature of the picture he is ultimately to obtain as a negative, for which purpose he must dodge, in or out, the legs of his tripod, or rotate the camera a little to one side or the other until he is satisfied with the pictorial effect.

When thus composing a picture it is well at first to do so without any stop or diaphragm being inserted in the lens, as the greatest possible illumination, quite irrespective of sharpness, is here desirable. The proper arrangement of the subject having been secured, next try and make the image as sharp as possible on the ground-glass, which is the second function performed by the focussing screen. It is quite possible that the image may be sharp in the centre and fall away, in respect to definition, towards the sides. To rectify this insert the largest diaphragm and note the effect upon the image. One use of a diaphragm is to extend the area of sharp definition to the extreme edges, another being to extend the range of sharpness from a near to a distant object. Should the first diaphragm not give the marginal sharpness desired, then must each smaller in succession be tried until the sides are sufficiently well defined.

To permit of the image being clearly seen upon the ground-glass, a focussing cloth is necessary. This is an opaque square of black flexible fabric such as velvet, which, when thrown over the camera must be so capacious as to permit of its covering the head of the operator whose eyes must be at least ten inches from the focussing screen. This cloth, by preventing the light from behind from falling upon the ground-glass, permits of the image formed by the lens being distinctly seen, which without such an adjunct would not be the case. If the beginner is not gifted with very sharp sight he may with advantage have recourse to the aid of a small magnifying glass so as to ensure the utmost possible sharpness when focussing.

We now turn our attention to the plates. Having obtained a packet of dry plates the suitable size for the camera, they must be brought in a room into which not the slightest vestige of white light finds admission. Let the light proceed from a candle or lamp so carefully covered by deep ruby glass or ruby paper as to render impossible any ray from it escaping into the room, except those transmitted through the coloured screen. The faintest white light falling upon the plates, even for an instant, will cause them to fog and be rendered useless. Having opened the parcel, ascertain which is the coated side of the plate, and place it in the slide, face down, taking care to fasten down the back. Of course this may be done at any time, even one or two weeks or even months anterior to the time of using the plates in the camera, but special care must be taken that the slides containing the sensitive plates be kept away from the light in the interval, because no matter how closely fitting the various parts of the slide may appear to be, it is not impossible that a little light may be admitted. The precaution of keeping each "loaded" slide in a bag of black calico or an envelope of brown paper cannot be too strongly insisted upon.

It is in giving the exposure that the greatest errors will be perpetrated at first, and regarding this no rule can be given. If one second's exposure be given at first, the tyro will, upon developing the plate, ascertain whether this has been too much or too little. The mere act of exposing is simple. Having ascertained that the subject is focussed, cap the lens, remove the focussing screen, and insert the dark slide. Draw the shutter from the latter, and when all is ready uncap the lens for a second. Having replaced the shutter, remove the slide to the dark room.

There are two systems of development, one by iron and the other by pyrogallie acid. We shall describe the former first.

Having previously prepared, in separate bottles, a saturated solution of protosulphate of iron (saturated in the sense that the water can dissolve no more, and that there are undissolved crystals still lying on the bottom) and a saturated solution of neutral oxalate of potash, and having previously added two or three drops of sulphuric acid per pint to the iron solution to ensure acidity, lay the plate down, face up, in a flat developing dish, and pour over it enough water to cover the surface. Allow this to stand, carefully protected from the red light, while three drachms (or parts, according to the quantity required) of the iron solution are poured into a graduate, to which is then added a quantity of the potassium oxalate solution sufficient to make two measured ounces. The mixing of these two solutions, colourless in themselves or nearly so, produces a red fluid, the colour of which, however, will scarcely be observed in the red operating light. Now, tilting up the dish containing the negative, pour off the

water, and then pour in the ferrous-oxalate developer which has just been mixed. Rock the dish gently backwards and forwards to ensure the liquid passing over the face of the plate, and if the exposure in the camera has been correct, an image will speedily begin to appear on the plate.

The sky and best lighted parts will show first, followed by those portions that were not so well lighted. By slow degrees the whole image will be out. It is desirable to continue the development until the half tones shall have become merged into the high lights, scarcely anything remaining visible but the deepest details. At this stage the plate must be removed from the dish and subjected to a rinsing with water. When held up against the light all the details will now be seen. If these appear to be imperfect it is not yet too late to return the plate to the developing dish for further treatment.

When it is believed that the whole details have been brought out in a sufficient degree, it is rinsed, and then transferred to a dish containing fixing solution. This may consist either of cyanide of potassium or hyposulphite of soda. There are several reasons why the latter may be preferred. In this case a degree of strength of four ounces to the pint of water will be found to make a fixing bath of average strength. By immersion in this solution the white coating of the plate disappears; this can only be properly ascertained by lifting up the negative and examining it from the under or plain glass side. It must remain in this solution a little longer than suffices for ensuring the removal of the white film, after which it is placed in a dish of water to secure the removal of the hyposulphite of soda. In this dish the water must be very frequently changed. It is difficult to say precisely how long a negative should be washed, but it is safe to leave it in changing water for half an hour.

After this it is reared on end to dry.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 369.—“Improvements in Printing Frames for Printing Photographs and the like.” Communicated by J. C. A. Hermitte, J. Y. JOHNSON.—*Dated January 10, 1887.*

PATENTS COMPLETED.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS AND STANDS.

No. 2039. HARRY LUCAS, 32, Little King-street, Birmingham.—*February 12, 1886.*

My present application is based on my provisional specification, No. 11,317, 1885.

I propose making my camera wholly or partly of metal, with the ordinary bellows body and a loose base, and I attach the camera to the base by an improved method. I make what I may conveniently describe as two grooves, one near each end of the base and running crosswise on it. These grooves stand above the base, and face the ends near which they are placed. The back and front of the camera fit into these grooves, and are fixed by screws.

The camera stand I make of telescopic tubes, with improved methods of adjusting and fixing them, so as to regulate the height of the stand. By one method I put a female screw on the end of one tube which receives another, and on the inner tube, a free male screwed collar, with one or more cuts across the threads.

The screw collar engages with the female screw, and binds the inner tube at any desired part.

By another method, I put a spring catch or bolt on one tube, which shoots into a hole or notch on the next tube, when the tubes are drawn out to the proper position.

IMPROVEMENTS IN OR CONNECTED WITH PHOTOGRAPHIC LENSES.

No. 2068. LOUIS GEOFFROY, 59, Frith-street, Soho, and WILLIAM FREDERICK BARTON MASSEY-MAINWARING, 30, Grosvenor-place, Middlesex.—*February 12, 1886.*

The improvement consists in arranging a binocular camera in such a manner as to produce one image on the sensitised plate, instead of two as heretofore employed for stereoscopic pictures, and by the simultaneous impression of two dissimilar pictures in the same place to obtain a more natural and increased relief in a single picture or view than in one taken by a single lens.

In carrying the invention into effect, the back lenses of stereoscopic cameras are so formed that their last surfaces are prismatic in such a degree as to converge the centres of their images to one point on the receiving sensitive surface; or the same result may be produced by means of separate prisms placed near the back of the lenses.

According to another arrangement we may employ such portions of a lens of greater diameter than the width of the eyes as correspond to the positions of the lenses in a stereoscopic camera, and thus obtain the desired result by the refraction of two images to one point on the sensitive surface.

Or we may obtain a similar direction of the rays of light to this end by the use of suitably inclined mirrors, or by any other optical arrangement by which the same result may be obtained.

IMPROVEMENTS IN PHOTOGRAPHIC CAMERAS.

No. 2365. CHARLES DAY DURNFORD, Ordnance Store Department, Edinburgh.—*February 18, 1886.*

THE object of my invention is to provide for use an extremely convenient, effective, and compact photographic camera, with which object I construct this camera as hereinafter described.

The base of the camera is made in two parts, which are hinged together, and on the edge of one of these parts is erected the front of the camera, which front may be made in any convenient manner with the usual aperture lens and other appliances. The front part of the base is of sufficient size to enable the hinder part thereof to be turned up to enclose the back and other parts of the camera when desired, and a rod is fitted which may slide in one or more sockets on or in the base, and enter a bracket formed thereon on the front part or edge of the base to make the whole base very rigid, and to assist in producing this effect the end of the rod and the aperture in the bracket into which the same enters are preferably bevelled, whereby the rod is wedged in position. To the rear of the base on each side are fitted extension pieces, which are so hinged as to be capable of folding in alongside the rear edge of the base and of being opened out in continuation of the lines of the sides of the base in all positions, being on the same plane therewith, and on these two extension pieces may be the usual racks for the extension of the camera. When these two pieces are closed alongside the rear edge of the base, the same may be held in position by a T piece on the end of the aforesaid sliding rod, or otherwise, and when these two pieces are opened out the same may be held in position by blocks or chocks on the bottom of the back of the camera, or otherwise.

The back of the camera is made, as is usual, of a frame divided into two complete frames or parts, which are extensible the one to the other, but these two parts are not connected together by the ordinary transverse bar and other appliances, but by two preferably L shaped levers, one being on each side. One end of each lever is pivoted on a bracket projecting from one part of the back, while the other end is jointed in the proper position to the other part of the back, and a tail piece may be fitted on the rear side or elsewhere of the lever, which can work in a socket formed therefor and can act as a stiffener, and, if required, as a stop. A sliding stop also is preferably fitted to clamp the lever when the two parts of the back have been duly separated, or are in other desired positions in respect of each other, and the parts of the stop and lever so in conjunction are preferably bevelled, whereby the stop and the lever are wedged in position. On the top of the back may be fitted a suitable slotted bracket, projecting from one part of the back, in which slot travels a pin fixed in the other part of the back, and a sliding stop can also be fitted to clamp this bracket on both, being similar bevelled edges for the purpose aforesaid.

The bellows of the camera are formed in the usual manner, but to render unnecessary the usual size and depth of the back frame of the camera required by reason of the very deep folds of the bellows all the rear or back parts of my bellows are formed with extremely shallow folds for such a distance as may be deemed necessary, and these extremely shallow folds may be either very gradually or suddenly or only comparatively suddenly increased in depth, with the object of not intercepting the rays of light from the lens, thus permitting the use of a smaller back than is usual.

The dark slide may be fitted to and used with the back of the camera in any usual manner or may conveniently be supported in position by an extension of or a ledge on the bottom of the back, being retained thereon by studs and sockets, while the upper edge of the slide could be held by a catch or otherwise, and the sensitive plates can be held in the slide in any usual or convenient manner.

The camera so made as aforesaid can be hinged on one edge of the top or table of the tripod or other support, or still more conveniently the camera can be secured as usual to this top or table, which top or table can be hinged to the tripod or support at and on one side, and in either case the camera could be maintained in position by an hinged stay passing through a socket on the opposite side of the top or table or of the tripod itself or elsewhere, in which socket the stay could be secured by a clamping screw or other appliance, and on the loosening thereof the camera can regain its horizontal position, or the camera can be otherwise supported in its vertical position.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at the ordinary monthly meeting of the above Society, held at 5A, Pall Mall East, London, Mr. James Glaisher, F.R.S., President, occupied the chair.

Messrs. C. G. Collins, James Martin, Hedley M. Smith, and the Rev. W. D. Fenning were elected members of the Society.

The CHAIRMAN said that a paper having failed them at the last moment

Captain Abney had come forward with something to occupy their attention, and the meeting was indebted to him very much for his kindness.

Captain W. DE W. ABNEY, F.R.S., here exhibited one of that class of photometers in which two beams are taken from the same source of light to make the measurements, so that the variations of the light being equal in both beams, such variations do not affect the accuracy of the results. His photometer consisted of a paraffine flame with a lens about one foot off; a transparent print on glass of an image of the sensitometer screen was placed close to this lens; a second lens, about a foot further on, threw an image of the slide upon a screen about four or five feet off; close in front of this screen was an upright rod casting a shadow across the image. Another beam of light from the paraffine flame was received upon a plane mirror, and reflected thereby upon the same screen, upon which, therefore, fell altogether two shadows of the rod. In the path of the reflected beam of light was a circular disc with sectors, which opened and closed. This wheel was made to rotate when required by means of electro-magnetic apparatus, and by adjusting the size of the apertures in the disc, the two shadows of the rod upon the screen could be brought to the same intensity. The readings of the photometer were in terms of the dimensions of the apertures at the times when the two shadows were equal. The paper was entitled *A Measure of the Densities of Photographic Deposits, with some Remarks on Sensitometers*. The author said that if he took a plate which had been "sensitometered," and wished to ascertain its photographic value by visual methods, how was he to proceed? He usually adopted Rumford's principle, applied by means of the apparatus before them, to which he had referred last year when he made the statement to the Society that he had an improved method of measuring the intensities of coloured lights, and one that was better than the employment of a candle flame. In photographic investigations it enabled him to bring any part of the photographic image into the centre of the field, and when there to measure its density independently of possible variations in the source of light. When the densest parts of negatives are dealt with, it was necessary to use a stronger light. For anything above five degrees the photometer before them was very accurate indeed. He exhibited a curve of the relative intensity of a negative taken under Spurge's sensitometer. It was nearly a straight line, and by further experiments he had found out that the optical and photographic values of his particular negatives were almost absolutely identical. He thought a good sensitometer screen could be made by developing with ferrous oxalate, containing a little bromide of potassium. He had compared the optical with the photographic values by means of platinotype paper, which answered well except at one end of the scale, where it gave feeble blacks, perhaps in consequence of having been too thinly coated. He thought Spurge's sensitometer to be the most accurate one in existence, although in some respects, perhaps, not so convenient as other instruments.

The CHAIRMAN asked if the standard candle, or Sir William Harcourt's light, were likely to be superseded as standards of measurement?

Captain ABNEY said that a Committee of the British Association was dealing with the subject of a standard of light. He hoped they would decide upon something before long, but it was a very difficult subject.

Mr. FRIESE GREENE asked whether Rumford's measurements, taken by means of two candles, would not be simpler than the plan before them?

Captain ABNEY replied that, with the candles, only the general intensity of the image could be taken, and not the intensity of any particular portion.

Mr. W. F. DOXKIN asked whether the longer path through which one of the beams of light travelled did not affect the results?

Captain ABNEY replied that it did not. The apparatus would not enable him to ascertain the intensity of the light; it would only let him know the density of any part of the negative through which the light passed. Five years ago the late Dr. Guthrie had a photometer made on the principle of that before them, and they worked at the subject together.

Mr. ARNOLD SPILLER said that the device for opening and closing the sectors while the disc itself was revolving was very ingenious; would Captain Abney describe it?

Captain ABNEY did so, but the details would be inexplicable without the aid of diagrams.

Mr. W. K. BURTON, C.E., said that the commercial sensitometers he had used were a weariness of the flesh, they differed so from each other.

Mr. H. TRUMAN WOOD asked whether Captain Abney could use the apparatus before them with the grease-spot photometric indicator, for the distance of the mirror from the lamp did not seem to matter much?

Captain ABNEY replied that he could do it, but should then use a lens.

Mr. W. BEDFORD asked what hopes there were of obtaining a standard photographic screen and a standard light.

Captain ABNEY said that they could only take the existing standards of light, of which he believed Siemens's to be the best. He could not recommend a phosphorescent screen; he had two which varied greatly and had misled him in things he wanted to know. He was on the British Association Committee and had been working for three years at experiments on standards of light; he hoped that an electrical standard of light would come out before long.

Mr. T. BOLAS said that the chief feature of the apparatus before them was that it was independent of variations in the source of light, and gave the power of measuring the densities of different parts of negatives.

After a vote of thanks to Captain Abney, Messrs. Ince and Francis Cobb were appointed Auditors, and Messrs. W. Bedford, Addenbrooke, F. Cobb, W. K. Burton, W. M. Ashman, and George Scamell were appointed Secretaries.

The CHAIRMAN announced that all nominations for members of Council must be sent in on or before Monday next. Those arriving on Tuesday will be rejected.

The proceedings then closed.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, January 6, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. William Belford presided.

The CHAIRMAN read a letter from Mr. York to Mr. Henderson, calling

attention to two negatives, one of which had been kept in a dark slide after exposure, and another, taken at the same time, had been wrapped in paper; the paper had had an accelerating effect after exposure, as proved on developing the two pictures.

Mr. A. L. HENDERSON thought that perhaps the paper was a little damp; the accelerated negative was not fogged.

Mr. J. B. B. WELLINGTON then read a paper upon *Orthochromatic Photography* [see page 21].

The CHAIRMAN remarked that it was a clear paper, free from vague statements; the question remained how to make the plates keep.

Mr. B. J. EDWARDS said that it was a curious thing that up to this time no practical notice has been taken in England of discoveries lying at our very doors. It is a fact that at the present time all the principal work done in Paris in the copying of paintings is orthochromatic, and at the Inventions Exhibition at South Kensington were some of Taillier's results, which did not attract much attention from photographers but won a silver medal. Nearly all orthochromatic plates contain a fluoresceine of some kind, as can be seen on reference to the patents taken out in this country during the last three or four years. Colonel Waterhouse was the original discoverer of the use of eosine as a colour sensitiser; he did this in 1876, but did not find out how to apply it to gelatinobromide plates; in 1882 he was followed by Taillier, and in 1884 by Vogel. Mr. Wellington had just recommended the use of ammonia and alcohol with the sensitiser, and Taillier in his patent mentions the necessity of using ammonia as a vehicle. In the preparation of orthochromatic plates it is necessary to get the right kind of eosine, for there are about thirty-five varieties altogether; it is also a fact that not every gelatinobromide plate can successfully be made orthochromatic, and it is likewise the case that an eosine which will work well with one kind of plate will sometimes not work well with another, consequently elements of uncertainty are present. He possessed some plates made by Taillier's process more than a year ago, and he believed that they were in as good condition as ever. There was nothing in the process to prevent the highest sensitiveness, and he thought that eosine properly applied would not be a source of danger to the keeping properties of the plates; he was making experiments in relation to the latter problem. He wished to draw attention to a coloured design and to orthochromatic prints therefrom, which he then laid upon the table.

Mr. W. E. DEBENHAM asked whether both the plates used for the negatives were employed with or without the yellow screen.

Mr. EDWARDS replied that he had been assured that both had been taken with the naked lens and no yellow screen; he had produced similar results himself in that way.

Mr. DEBENHAM said that Mr. Edwards had made a statement that eosine without ammonia was quite useless. The use of eosine in ammonia was a special claim in his patent. He (Mr. Debenham) had used eosine without ammonia, and specimens of the results, which he would now lay before the meeting, proved that under those conditions eosine had a very decided effect. He found that not every plate was suited for the process, and that when he used the yellow glass as well as the eosine he obtained the full advantage of the two. He had found that an ordinary plate containing an iodide did not succeed when used with an eosine bath, but that a plate prepared with pure bromide answered the purpose; his experience, however, was very limited.

Mr. J. R. GOTZ remarked that Dr. Vogel had told him that there should be no iodide in the plate.

Mr. WELLINGTON said that in his experiments the emulsion contained one per cent. of iodide.

Mr. EDWARDS stated that with some samples of eosine he was using a comparatively large proportion of iodide.

Mr. W. H. HYSLOP asked whether more than four of the eosines mentioned were made commercially. Manufacturers told him that practically only four were in the market.

Mr. EDWARDS said that those four were liable to vary indefinitely.

Mr. HENDERSON stated that up to the day before he had been a great sceptic as to orthochromatic photography, because those commercial plates which he had tried did not give the alleged results, but the day before Mr. Wellington had sent him some plates which had caused him to alter his opinion. To try the properties of orthochromatic plates fairly the solar spectrum should be used; the colours of paintings were far from optically pure, and in different pictures varied indefinitely. By using very rapid plates and a proper yellow screen he obtained good orthochromatic results.

Mr. EDWARDS said that all copies of the coloured design sent out with Taillier's plates were printed with the same colours, so the prints were of equal value for testing the colour sensitiveness of plates. Good orthochromatic plates work best with a yellow screen unless they are first made very sensitive to yellow light. The real advantage of orthochromatic plates is in everyday work, for they certainly give a more correct scale than the plates in ordinary use; in landscapes they give clouds, sky, and foreground in more true relation, and trees are more faithfully rendered; in studio they make a greater difference in the rendering of textures than of smooth surfaces—at least, he thought such to be the case. Orthochromatic negatives need less retouching than others. They do not need a much longer exposure than other plates, and can be used when the light is yellow or the weather foggy; by daylight an orthochromatic plate is nearly twenty times more sensitive than an ordinary plate.

Mr. A. H. HARMAN remarked that he had had no experience with orthochromatic plates; Mr. Edwards was a manufacturer of them and he (Mr. Harman) was not, but he thought that they were all of opinion that it was a very valuable process, specially useful in large towns to enable photographers to take negatives in a bad light. He thought the yellow screen to be a great disadvantage, and if Mr. Edwards' plates could be used without it, it would be an improvement.

Mr. A. COWAN said that in all the pictures laid before them that evening orthochromatic plates seemed to render the reds worse than did ordinary plates.

Mr. HARMAN remarked about Mr. Debenham's pictures, that with the exception of the rendering of an orange, he thought that altogether the print from the ordinary plate was the best of the two.

Mr. DEBENHAM believed that idea to be due merely to one having been printed a little darker than the other.

Mr. HENDERSON had once obtained orthochromatic effects by adding sulphide of calcium to the emulsion, but the plates would not keep.

Mr. HYSLOP had found Dixon's to work better than Tailfer's plates, when used without a yellow screen.

Mr. HARMAN did not consider the process to be of much value if the plates would not keep well.

Mr. GOTZ said that plate makers accept it as a rule that plates prepared by dipping in eosine do not keep, and that those prepared with eosine in the emulsion do keep; the dipped plates, however, are quick, and the others are slow. Dr. Vogel and others had told him so.

Mr. EDWARDS stated that it was not altogether a fact that orthochromatic plates were slow; they might be slow at first, but could be quickened afterwards.

Mr. WELLINGTON said that his experience was at variance with the statement of Mr. Gotz; his plates proved to be far more rapid when they were not dipped.

Mr. W. H. PRESTWICH was of opinion that if orthochromatic plates came into general use, it might be advantageous to have studies of yellow glass, to give a better scale.

Mr. HENDERSON wished that Mr. Edwards would bring some of his orthochromatic plates to a meeting of the Association, and use them himself, to test for rapidity against his (Mr. Henderson's) plates by gaslight.

Mr. EDWARDS said that if Mr. Henderson would make his very rapid plates orthochromatic, they would work ten times more quickly by gaslight.

Mr. DEBENHAM remarked that about a year ago Angerer remarked that very rapid plates were more orthochromatic than slow plates, so that to get good results it was only necessary to use exceedingly quick plates under yellow glass.

Mr. W. H. HARRISON had recently seen orthochromatic photography reduced to the extremest simplicity by Mr. Theophil D'Haoûw at Ghent University; he used neither eosine nor yellow glass, but waited until nearly twilight, when there were but few blue rays in the light, then placed the coloured objects in a room and far from the window, and photographed them upon ordinary quick plates, but with some such long exposure as twenty seconds. The blue colours in the object found little blue incident light to throw off, hence a vase of flowers of different colours gave a good orthochromatic scale on the negative plate.

The CHAIRMAN stated that Messrs. Dixon & Gray had brought the importance of the subject home to photographers at the last Photographic Exhibition. Mr. Wellington had done more than the majority of experimenters in the subject, by giving his methods and results so fully; if he had published those results a little sooner he would have been in advance of Dr. Vogel.

Mr. J. HUBERT had received some of Dr. Liesegang's collodio-chloride paper, and would give a demonstration to the Association with it on the first Thursday in next month. It gave better half tones than could be obtained with albumenised paper.

Mr. HENDERSON said that Mr. W. Cobb had some collodio-chloride prints about twenty years old, and they exhibited no symptom of change.

The meeting then broke up.

CAMERA CLUB.

THE meeting at the Camera Club, on Thursday, January 6, was a members' lantern-slide meeting. Slides were shown by Messrs. J. H. Knight, J. Gale, Barclay, and Dresser. A number of those recently received in exchange from the American Societies were also put through the lantern.

The chief feature of the evening was the exhibition of a series of fifty slides, accompanied by a very interesting lecture by Mr. J. H. Knight, in description of scenes, manners, and customs in Madeira.

On Thursday, January 20, the subject for the evening will be, *The Development of Bromide Paper Prints*, the discussion to be opened by the reading of a communication from Mr. Andrew Pringle. Meeting at seven p.m.; paper read at eight.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE annual lantern meeting of this Society was held on Thursday, the 6th instant, at the large hall of the Society of Arts, John-street, Adelphi, W.C., when Mr. T. Bolas, Vice-President, occupied the chair.

There was a very good attendance of members and friends, and, as usual upon these occasions, many ladies were present.

The CHAIRMAN, in opening the proceedings, said his duties were remarkably easy, inasmuch as lantern displays of the kind they were assembled to witness did not require any talking. There was a point, however, to which attention might be directed on account of novelty, and that was the mode of illumination about to be employed. It was an electric arrangement supplied from a dynamo machine working in the basement, and this was supplemented with a series of storage batteries. One of Siemens's lamps was fitted to the lantern, and an illumination equal to something between three and four thousand candles would be obtained. The reading lamp, a Swan & Edison incandescent, was in the system, as also were all the lights in the building. Mr. G. Davenport, who would work the lantern, had devised a new slide carrier that was both simple and ingenious, and this would be used for the first time that evening.

More than two hundred slides were then exhibited upon the large screen, a disc of eighteen feet being projected. The splendid illumination obtained showed that many of the transparencies sent for exhibition had been prepared for a much less intense light, but, on the whole, the display was eminently satisfactory.

Mr. C. Pilkington showed several well-known views near London, all of which were coloured with very good effect.

Mr. W. M. Ayres, as usual, illustrated the capabilities of wet collodion transparencies toned with platinum and gold; many of them were, however, much colder in tone than it is customary to produce.

Mr. T. Charters White divided attention equally between photo-micrographs and the less difficult studies by the wayside.

Mr. F. A. Bridge showed a few of his Belgian series.

Mr. J. Gale illustrated scenes in Sussex with a magnificent series of wet collodion transparencies from gelatine negatives, which elicited much applause.

Mr. W. Wheeler followed with a short series of Aston Hall, Warwickshire.

Mr. J. B. B. Wellington represented the collodio-bromide process with a large number of slides.

Mr. George Smith exhibited a number of various subjects produced in Woodburytype.

Mr. S. A. Allen showed several subjects wherein both positives and negatives had been made on commercial gelatine plates.

Messrs. F. York & Son sent two of their lecture series, which afforded much amusement to the juveniles present.

Mr. F. A. Bridge gave the readings sent therewith.

Mr. W. England showed a series of statuary subjects.

The principal peculiarity in Mr. G. Davenport's new patent slide consists in a prolongation of the metallic runner that carries the slides. This terminates in a certain screen, that in travelling along the guides covers the lens. During the brief period an automatic change of subjects takes place, the effect of which upon the screen was exceedingly good. At the termination the usual vote of thanks was accorded.

GLOSSOP DALE PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting was held at the Society's Rooms, Norfolk-square, on the 4th instant.—Mr. Greaves in the chair.

The minutes of the last meeting were read and confirmed.

The HON. SECRETARY announced that he had received forms of application for space at the forthcoming Manchester Exhibition for members wishing to exhibit.

It was resolved that the Society give a lantern entertainment to the inmates of the Glossop Workhouse, subject to the approval and consent of the Board of Guardians.

Mr. S. D. McKellen and Mr. Chas. Harris, of Manchester, having offered to contribute apparatus and pictures respectively towards the exhibition and *soirée*, it was agreed to accept the same.

Several minor arrangements were then discussed for the forthcoming *soirée*.

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Association, held on Thursday, January 6, took the form of a lantern exhibition, and was largely attended by the members and their friends.

A very interesting series of slides, entitled *In and about Arbroath*, was shown by Mr. J. Geddes, who delivered a running description of the principal points of interest.

Mr. Geddes objects to the $3\frac{1}{2} \times 3\frac{1}{2}$ size, which has so long been thought necessary, and makes all his slides and plates $6\frac{1}{2} \times 3\frac{1}{2}$; this size of picture being pushed slowly through the carrier has a very good effect, and gives a better idea of the subject than the regulation-sized slide. His transparencies were made some on wet and some on dry plates.

A series of slides sent by Mr. Pumphrey, Birmingham, was next exhibited.

Mr. Andrew Pringle will lecture in the Kinnaird Hall, Dundee, under the auspices of this Association, in the beginning of February. The subject is, *A Tour round the World*, illustrated by a series of lantern photographs.

Correspondence.

✉ Correspondents should never write on both sides of the paper.

JANUARY MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—PRINTING FRAMES REPLACED.—SIMPLE SHUTTER.—LANDSCAPES OBTAINED WITHOUT A LENS.—PHOTO-TOPOGRAPHIC CAMERA.—MODIFIED STEREOSCOPE.—EASTMAN'S ROLLER.—CHLORIDE OF SODIUM AS AN ACCELERATOR.—INSTANTANEOUS CHRONOMETRIC SHUTTER.—PROGRESS IN ELECTRIC LIGHTING.

The Photographic Society of France held their monthly meeting on Friday evening last, the 7th instant, M. Davanne in the chair.

M. Gorde made a presentation of a photographic accessory, which he has named *glissière*. This object has been invented in order to do away with the heavy and expensive printing presses now employed to obtain paper positives. The instrument is composed of two metal bands sliding one upon the other, being about one-sixteenth of an inch thick and one and a quarter inch wide. The two ends are curved so as to form two kinds of crochets or hooks. In looking at Diagram I. the

DIAGRAM I.

form of this glissière can be seen. A and B form the two pieces of brass band sliding one upon the other (probably on this account its name

of "glissière"), held together at DD so as to be lengthened or shortened at will; moreover, as can be seen, this glissière takes the form of a curve and acts as a strong spring.

In looking at Diagram II. its use in photography can easily be seen

DIAGRAM II.

and understood. E represents a glass negative, on which the instrument is fixed.

To print a paper proof the negative is taken and the sensitised paper laid upon it; a padding of blotting-paper is now placed upon the sensitised paper; a glass plate, of the exact size as the negative, is now put upon the blotting-paper (this glass plate has been cut into two parts). The curved point of the glissière is now put on one of the sides, and the spring forced down until the other curved point goes over the other side of the negative and so holds the whole together. Another spring is put upon the other half of the negative, and the whole is ready to put out to light. In order to examine the print to see if it is sufficiently printed, the glissière is lengthened. By pulling it out at C it leaves the plate immediately, and takes its curved form as in Diagram I. The piece of cut glass is taken off the print, and if not sufficiently printed the glissière is put on again with the greatest ease.

To sum up, the glissières can replace with advantage the two springs of the printing frame, at the same time doing away with the latter, which is both cumbersome and expensive; whereas, as much as I could learn, the glissières can be obtained at a very cheap rate, and are light and easy to employ.

The same gentleman made another presentation—that of a rapid shutter, to be used in the centre of the lens. This shutter would not be worthy of notice, when compared with other sumptuous and excellent apparatus now in the market, if it were not that the instrument is easy and simple, so that amateurs and beginners can make it at home.

Diagram III.—A represents a round brass tube, having a slit in it nearly from top to bottom. In the interior of this tube is a piston, the rod of which is exterior and forms the obturator, having the shape of a

DIAGRAM III.

DIAGRAM IV.

diaphragm. The piston moves up and down this tube by two mechanical contrivances. Firstly: It is forced upwards by means of an indiarubber tripart bellows (see Diagram IV.). This bellows is inflated by means of an indiarubber ball, D. Secondly: The piston is forced downwards as soon as the hand of the operator ceases to squeeze the ball, by means of a thin steel spring placed in the top of the tube, E. F represents the obturator at rest; G shows the obturator fully open. A long or short exposure can be obtained at the will of the operator.

M. Colson, Capitaine du Génie, exhibited some very remarkable proofs obtained by him in a camera without the aid of a lens. He had a piece of brass perforated by a pinhole, and by the immission of the reflected rays from the landscape through this hole he gained a sharp and finely delineated view without any distortion whatever.

In making inquiries I learnt that Capitaine Colson exposed about two minutes; so that if the sensitiveness of plates continue in the same ratio as they have done within the last few years, we may hope sooner or later to discard that expensive auxiliary, the lens, from our studios.

A captain in the Spanish army exhibited a camera which he employs for photo-topographic purposes. A great discussion took place as to its advantages and its defects over other and similar instruments now in use.

M. le Comte Alberie du Chastel presented a modified stereoscope. This gentleman informed the Society that he had been struck with the unnatural appearance of stereoscopic pictures caused in a great measure, he said, by the old-fashioned system of cutting them to a fixed size, which up to the present had been accepted as the best form for such

pictures. Generally, he said, the stereoscopic pictures are obtained on a half-plate, and when cut a large part of the foreground is thrown away as useless, and, said he, it was very natural to do so, as the perspective appears to be exaggerated in the extreme; but when the double view is put uncut into the stereoscope one would be surprised to see how that instrument would harmonise the lines and correct the faulty perspective. Several views were passed round, some cut to the ordinary size and others cut much longer. The general opinion was that a great advantage was gained by leaving more foreground to the stereoscopic proofs, and advised opticians to enlarge their apparatus so as to admit a larger slide.

M. Nadar presented Eastman's roller slide, and explained its working to the members.

M. Franck informed the Society that he had continued his experiments as to the value of common salt as an accelerator in the development of gelatino-bromide of silver plates, and was more and more an advocate for its employment. His attention was drawn to its use by THE BRITISH JOURNAL OF PHOTOGRAPHY announcing that it was a cure for frilling; in using it for this purpose he found that not only did it act well for this purpose, but that it had other qualities—that of being an accelerator. After having made several experiments himself, he requested M. Audra to repeat the same. M. Audra said he was perfectly convinced that sodium chloride was a powerful accelerator. M. Franck laid before the members several plates which had been exposed the same time, and of which some had been developed in the ordinary way with ferrous oxalate, the others with the addition of common salt. All those developed by the addition of the sodium chloride were well developed, full of detail, and dense. Those developed simply by the ferrous oxalate had only a shadow of a picture, although M. Franck said that they had been developed to the utmost to get out a full image.

A member said he had tried the method but without any similar result; he had used pure sodium chloride. The answer given was that perhaps a chemically pure salt was not so advantageous as the common salt, which contained, as every one knew, lime, magnesium, and other products, which might be the principal agents for this phenomenon.

M. Franck, after giving *in extenso* the history of the manufacture of salt upon the sea-coast of France, then counselled the member to try again with ordinary commercial salt.

M. Fabre exhibited a very nicely constructed instantaneous shutter—chronometric in its working, and having several advantages over that of Beca. It is much lighter, less liable to get out of repair, and above all much cheaper. It consists of a trap which rises, and which when it gets to a certain height lets another down as soon as the clockwork gets to a certain point.

Electric lighting of the sitter has made giant strides in Paris, where the light of Phœbus is completely replaced during the winter by the electric light with triple reflection. To M. Chary, the successor of M. Walery, is due the credit of this innovation. I need not enter into the description of this establishment; the interior decorations, the furniture, and the taste displayed are worthy of admiration, and make a little palace of this abode of art. M. Chary is no longer tributary to the orb of day; he can operate at any hour and at any moment. He no longer requires a glazed roof; portraits can be made by him in a cellar as well as in the best-lighted studio; he obtains with the electric light the same quality and the same perfection in the negative as if obtained with the sun's rays. I had the advantage to be present the other day, and can certify that all M. Chary claims for his modification of the electric light for portraiture is quite true. I will endeavour to give an idea of his working. The customer is introduced into a magnificent saloon lighted up by incandescent lamps; here the sitter's eyes become accustomed to the glare of the electric light. At a given moment a few of these incandescent lamps are extinguished, and a powerful arc lamp throws out its rays. This lamp is just behind the sitter, and whose portrait could be taken without his or her being aware of the change in the light had not the sitter been warned by the operator that the exposure had begun. The rays from the arc lamp—placed as I said behind the sitter—are reflected by screens upon the model, so as it were to inundate the latter with refulgent, but, at the same time, soft and genial rays.

M. Chary made the portrait of Madame Stebbing, and I send a copy to the Editors for the office of THE BRITISH JOURNAL OF PHOTOGRAPHY.* The proprietor showed me many portraits obtained by the electric light as modified by himself, and it would be impossible for the most experienced photographer to distinguish that they had been obtained by artificial light.

PROF. E. STEBBING.

25, Rue des Apennins, Paris.

RECONSTRUCTION OF THE NORTH LONDON AMATEUR PHOTOGRAPHIC ASSOCIATION.

To the EDITORS.

GENTLEMEN,—It has been decided to change the name of the North London Amateur Photographic Association to the "North London Photographic Society."

This Association, which had its origin in a very humble manner, has now grown far beyond the expectations of its promoters, and the members

* We have received the portrait. Thanks.—EDS.

consider that it is no longer wise to observe any exclusiveness in the admission of members. Therefore, believing that it will be mutually to the benefit of professional, amateur, and dealer, to have a general photographic debating society in the northern suburbs, have decided to throw open its doors and admit every one interested in the advancement of photography.

As it will be necessary to form new rules and to elect officers for the present year, an open meeting will be held at Myddelton Hall, Upper-street, Islington, on Tuesday, the 18th instant, at eight p.m., and any one wishing to join the Society in its reconstructed form is invited to attend and take part in the business of the evening.—I am, yours, &c.,

H. M. SMITH, *Hon. Secretary N.L.A.P.A.*

5, Beatrice-road, Stroud Green, N.

THE COUNCIL OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

To the EDITORS.

GENTLEMEN,—The record of the attendances of the members of Council of the Photographic Society of Great Britain at the Council meetings during the past year, as published in the December number of the *Photographic Journal*, should be carefully studied by the members, and especially the country members of the Society; and as the matter is, or should be, of some importance not only to the members themselves but to all who are interested in the Society, being in fact as well as in name the "Parent Society," I venture to ask space for the insertion of the list, rearranged, but not altered, and for a few remarks thereon.

OF A POSSIBLE EIGHT ATTENDANCES.

*The President attended	8	Abney, W. de W., attended	1
Davis, T. S.	8	Cobb, W.	4
*Bird, W. S.	7	Spiller, J.	3
*Donkin, W. F.	7	Cadett, J.	2
Bedford, W.	7	*Robinson, H. P.	1
Bolas, T.	7	*Bedford, F.	1
Blanchard, V.	6	Bolton, W. B.	none
England, W.	5	*Mayall, J. E.	3
Cowan, A.	5	*Paget, J.	3
Warnerke, L.	5	*Wortley, H. Stuart	3

OF A POSSIBLE SIX ATTENDANCES.

Addenbrooke, G. L.	5	Wood, H. Trueman	1
Emerson, P. H.			2

Retiring members are marked *.

It is gratifying that the veteran President has been blessed with sufficient health, and animated with sufficient zeal, to take one of the first places, and it is equally satisfactory to find that the Hon. Secretary and the Hon. Treasurer are only one step behind. Among the retiring members of the Council Mr. T. Bolas, with a creditable record of seven attendances, takes a very conspicuous place, the rest sharing with the retiring Vice-President the unenviable distinction of being absolutely at the bottom of the list.

Of course it is possible that these gentlemen, who have so utterly failed during the past year to perform the duties which they undertook on their election, may not have wilfully neglected those duties, but may have been prevented from their due performance by illness or unavoidable circumstances; but whichever way the matter is looked at, it is impossible to have a stronger argument against the continuance of the obsolete and absurd rule under which members of Council are elected, for better or for worse, practically for three years. At the time the present rules of the Society were passed there might have been some argument, although, even taking into consideration the then existing circumstances, it is hardly possible to conjecture what this could have been, in favour of this rule; but at the present time there is absolutely nothing to be said for it, but a great deal against it. It is manifestly unfair and inexpedient to saddle any one with a responsibility which is unnecessarily made to last until the year after next. The system, too, prevents that healthy interest, among the ordinary members of the Society, in the election of officers which would attach to a general election, with the result that, on the annual occurrence of six or seven vacancies, those to which retiring members are not re-elected are filled up by nominees of the Council, and the Council thus indirectly becomes a self-electing body. The consequence of this, the present state of affairs, is that, being practically beyond the reach of, and resenting any criticism from without, the Council institute no measure of reform and, as a body, oppose suggestions for any such, however much needed, as a possible step towards the curtailment of their self-assumed prerogative of absolute government.

It is hardly beyond the actual fact to say that the Society is entirely indebted to its annual exhibition for the apparent prosperity it enjoys. This exhibition, in spite of the adverse criticisms upon its management which have appeared in your *JOURNAL* and others, is on the whole far better conducted than might be expected; but, unfortunately, the undertaking seems utterly to exhaust the powers of the executive for the rest of the year, for in all other matters the Society is far behind even the little Society of my own county, and in the interest and importance of the matters brought forward at its meetings, and the manner of discussing the same, is immeasurably behind more than one of the other London Societies which I have had the privilege of visiting.—I am, yours, &c.,

January 8, 1887.

A COUNTRY MEMBER.

TOURISTS' CLUB.

To the EDITORS.

GENTLEMEN,—As many amateur photographers seem desirous of securing the benefits of a tourists' club, the Committee for managing the affairs of the Pedestrian and General Tourists' Club have had under their consideration the practicability of obtaining for amateur photographers the particular conveniences which they find necessary for their work when making photographing tours. The Committee are quite willing to do their best to make these arrangements for amateur photographers who may join the Pedestrian and General Tourists' Club if the number of such members is sufficient to cover the expenses necessarily incurred in making the arrangements.

I am not myself a photographer, but with the assistance of any suggestions which you, Gentlemen, or any of your correspondents, may make, and the valued co-operation of Mr. H. A. Hood Daniel, of Bristol, who has kindly undertaken to assist me, I do not fear being able to make perfectly satisfactory arrangements.—I am, yours, &c.,

H. COPE WEST, *Hon. Secretary Pedestrian and General Tourists' Club.*

39, Hamilton-square, Birkenhead.

PERMANENCE OF PRINTS.

To the EDITORS.

GENTLEMEN,—An important article appears in your last number bearing the signature of A. Pringle. Its primary object would appear to be to discredit platinotype, and thereby to annoy its great champion, Mr. H. Berkeley. I feel sure that the introduction of a personal element into scientific discussions such as these is condemned by the great majority of your readers, and looked upon by them as a great waste of valuable space.

Having therefore entered a protest against the spirit in which the controversy has been carried on, I will ask leave to make a few remarks on what is the practical outcome of Mr. Pringle's last communication. Whatever effect it may have on the future of platinotype printing I will leave aside, as I am sure Mr. Berkeley will have something to say on this matter, but with regard to developed gelatino-bromide prints I fear it has given the now favourite process a blow from which it will scarcely recover.

To find that prints which seemed to possess so many reasons to make us hope they were permanent are considerably injured by the action of sulphuretted hydrogen, is certainly a fact to shake our faith in their permanency, but if, as I understand, the yellowness affects the whole surface of the print, I fear the process is reduced to exactly the same level as printing on albumenised paper. This yellowness is a clear proof that there remains in the gelatine film or in the paper itself some silver compound of whose nature we are still in complete ignorance, and which is not, as supposed by some, an *albuminate of silver*. There should remain in the whites of the picture nothing but the gelatine film that held the salt of silver. The moment a salt insoluble in the fixing solution remains the chances of permanency become very doubtful, and I therefore consider the yellowing of the whites of a picture a far more dangerous symptom than a change of colour in the substance forming the image.

Unfortunately from Mr. Pringle's experiments, it appears that it is when the finished prints have the *purest whites* that they contain the most certain germs of future destruction. I feel doubly sorry for these results, as it must seriously affect the position of our paper negatives, which, of course, must share the fate of positives by the same process. One can scarcely see that any amount of care or washing can ensure us against the *danger* of fading any more than with albumenised prints.

I regret that Mr. Pringle did not submit to the same test an ordinary engraving on white paper. This would have made it certain that the cause of fading was not in the paper itself. The fault could then be easily remedied, as the fine engravings in the illustrated annuals of forty years ago are still as fresh as ever, proving that pure paper can be had.

Perhaps, however, after all, the failure of a process on which we were beginning to count too much may serve as a fresh encouragement to clever brains to seek out some perfect printing process that will give a chance of longevity to the products of our now nearly perfect negatives.—I am, yours, &c.,

GEORGE MANSFIELD.

Notts.

To the EDITORS.

GENTLEMEN,—Mr. Pringle's paper on *Sulphuration of Bromide and Platinum Prints* is, if not quite conclusive evidence against the latter, at least comforting to workers on bromide (especially for enlargements), as it appears to be as reasonably permanent as any other process we have, and, to amateurs at least, is so convenient, in consequence of the possibility of using it by gaslight for printing from our negatives on winter evenings.

But there is another test of the two papers which, though of a slower and less violent kind, tells in the opposite direction to Mr. Pringle's conclusion.

If bromide and platinotype prints (unmounted) are put side by side into the same "showcase" in the way that unmounted prints are frequently exhibited, namely, with their corners tucked into slits cut into the paper

behind to hold them in position, and left there for a few weeks' exposure to daylight in a shop window, it will be found that the bromide prints will be considerably faded, *with the exception of the hidden corners*, whilst the platinotypes will remain unaltered. It may not always be so, and I hope it may be proved to be avoidable by very careful washing; but that is so like the treatment that many photographs have to undergo that it may be accepted as a practical test of permanency quite as thorough as immersion in sulphuretted hydrogen, which, though very severe, seems a satisfactory test where the prints stand it scathless.

The rich black tone of bromide paper prints, which is satisfactory in portraiture, especially in large heads, is somewhat dull and sombre for landscape pictures, and I, for one, do not understand why two bromide papers (like, for instance, Eastman's and the "Alpha" papers) should yield such totally different tints under the same developer.

Would you, gentlemen, kindly give us an article at your early convenience and explain *chemically* why a prolonged exposure and a weak developer will give a rich sepia brown tint on Alpha paper, whilst a shorter exposure and strong developer produce the same black tone as bromide paper gives, and *which* seems not to be amenable to the same treatment for variation of tint?

The tint of your illustration in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC this year is so artistic, and reminds one so much of a fine sepia drawing, that it has made me desirous of adopting such paper and process for future landscape work, and possibly many other amateurs may form the same idea, and it would be a source of great satisfaction to learn "the reason why" such a great variation of tint is obtainable in its chemical bearings, so that we may proceed to work with more certainty and confidence, and I think it is a question which has not yet been fully explained in the photographic journals.

Will Mr. Pringle also tackle the Alpha paper prints as well as the bromide ones in his future experiments, and give us the result? as they are a branch of the same bromide development process, equally worthy of being tested.

Our old preceptors in photography—Mr. Sutton amongst others—always taught us that *developed prints* must be more permanent than printed out chloride ones, and therefore, I presume, few persons will be prepared to suppose that our old friend albumenised chloride paper can possibly stand so severe a test of permanency as any developed silver process, be it bromide, Alpha, or (the supposed absolutely permanent) platinotype.

Let us hope that the fight which is sure to follow Mr. Pringle's opening cannonade will settle the question which is the more permanent process now extant.—I am, yours, &c., "Lux."

ON PROCESSES AND PERMANENCY—A REPLY.

To the EDITORS.

GENTLEMEN,—In reference to the correspondence which is proceeding, it appears to me that the two quite distinct questions, the permanency of the image and the unalterability of the support, form separate objects for discussion.

It is absolutely certain that if the image dies out, or "fades," or changes into one of two or more tints, the result must be disastrous and by no means pleasing; but if the *paper only* changes slightly in tint, the result may be borne with more equanimity. Indeed, as the "toning" of an engraving by "age" is generally considered by connoisseurs to be an advantage, one might put forward a similar plea for other pictures, somewhat engraving-like, when they too, by "age," have acquired "a tone."

But—to pass from generalities to platinotype—I do not think any papers, as such, now used have better capabilities for remaining white than the platinotype paper has. It, too, is "specially made" for the Company—if that is any advantage in this direction. As regards papers, "they all do it"—discolour more or less. If, however, a print, by whatever process made, is not properly cleared of the substances which have rendered it sensitive to light, the whiteness of the paper basis must suffer: if a carbon print contains traces of bichromate, it becomes greenish yellow, and if one of Mr. W. H. Walker's prints is not properly "fixed" he can tell you what will happen to it.

It has been a great difficulty to the Platinotype Company, owing, I suppose, partly to the great general ease with which the process is carried out and to its apparent simplicity, to induce workers to properly carry out the clearing of the prints. As the prints *look white*, perhaps, even on leaving the potassic oxalate, and certainly soon after being put into the "first" acid bath, some suppose that all the sensitiser is at this stage removed. A moment's thought will show that it is dislodged only, not entirely removed. One cannot wash thoroughly in dirty water; and if the acid bath contains sensitisers, so must the body of the print—a trace only, perhaps, but yet maybe enough to impair the purity of the whites.

The subsequent washing in plain water has not the efficacy of the acid baths. So, no matter how many baths are used, if they are not progressively clean—each fresher than the former—a complete removal of the salts is not to be looked for.

No doubt some platinotypes which are now impure in the "whites" have been turned out, but proper care would with ease have avoided the

calamity; the conditions of this form of permanency are known, if not, are readily ascertainable. But, even then, mind that only the paper basis has altered in tint; the images are as full and true in colour as ever they were.

All we can hope for from any "permanent" process is that the prints shall be in behaviour like engravings, *provided* the conditions for permanency, which are *known*, are carried out.

Having found common German collotypes taken to be platinotypes, and knowing that not a few confuse the bromide prints with platinotype, I should be quite prepared to hear *anything* as to the behaviour of the latter, but before I believed it I should require to see the print to which allusion was made. I do not allude to Mr. Walker's statement, as I have often called attention myself to the need for proper "clearing" of the prints, and not an *apparent* clearing only. It must also be remembered that the Platinotype Company do not make all the paper on which platinotype prints are made.

If the prints are "yellow from the very day of their creation," as stated by Mr. Walker, all I can say is, either they have not been cleared at all, or else the prints have been made upon decomposed and very badly kept or treated paper. This kind of statement is just another of the "red herring" variety which is continually being dragged across the scent.* The points of value in a permanent process are these: that it shall be *easy*, by the carrying out of *well-known* conditions, to turn out *any number* of prints the permanency of which the producer can *guarantee*.

The "definition" of Mr. Dunmore, which Mr. Walker quotes, is "admirable," if I read it aright; I had myself put forward a similar view. When Mr. Walker has furnished better proof that the "image he has set up" neither will partially disappear nor change in tint, either *before or after* the paper alters (as he admits it must alter) in tone, in fact, will remain intact so long as the paper is firm and presentable, he will have established upon a sounder basis the contention at which, I presume, he aims.

Must I inform Mr. Walker, and, it seems, Mr. Dunmore also, that there is no necessity for "completely," or even partially, "destroying the paper support" when testing with the solutions, &c.?—"violent tests" I alluded to. I believe that an albumen surface would be particularly resistant, and I know plain paper is quite sufficiently so. Gelatinised paper if "chrome alumed" would no doubt stand any sufficiently strong solutions. I call on no one to apply tests which will destroy the paper; the object is to find out whether the image is as permanent as the paper, and, if not, what degree of stability is likely to be secured.

The value of these tests to one who wishes to prove, at an *early stage*, the permanency of his prints, is due to the knowledge that if a print can withstand more or less concentrated solutions and gases, it must naturally also withstand the same substances when brought to bear in extremely attenuated condition, as in the air, through a period of *many years*.

I say that the evidence is very valuable to an inventor, and may add that Mr. Willis was careful to so test his prints on first producing them, and long before the date of Mr. John Spiller's well-known experiments on them. Mr. Willis wished to convince, and to *convince at once*, without waiting, just as some others are now wishing. It did not take long to convince me of the value of the process in this respect. But "we have changed all that" now, and permanency is to be taken "on faith," just as is the honesty of one's neighbour!

Naturally the bromide paper manufacturers would not seek to raise this controversy—I am quite with Mr. Walker there—but the action they have taken naturally gave rise to it. Is it in human nature to take things quietly when we find others claiming, and in some cases securing off hand, without proof, the hard-earned and well-earned reputation of other processes which have had to *demonstrate* the truth of their claim?

Where would have been the value of the Platinotype Company's claim several years ago—at the "outset"—had it not been able to point to (1) the great stability of platinum, and to (2) the unalterability of the prints in solutions most damaging to silver prints of all kinds? And what would have been the inference had platinum rings, coins, and spatulas been subject to tarnishing or to chemical change? Does Mr. A. Pringle, for instance, think there would have been found no "analogy" had such been the case?

The facts as they stand had been used by outsiders as "analogy" favourable to platinotype; logically, therefore, I presume the inclination would have been adverse if facts had been the other way. It will not do to reject or to accept a class of evidence just as it may clash with or fit in with our object.

And why this opportunism? The reason of it is this, that while the one process is *private* property the others are *public* property. Further into the mystery I need not go.

HERBERT B. BERKELEY.

(To be continued.)

RECEIVED TOO LATE FOR ALMANAC.—Committee of Geneva Photographic Society for 1887:—President: H. F. Boissonnas.—Vice-Presidents: E. Sautter and E. Fatio.

* If Mr. Walker's paper were exposed by mistake, or otherwise, over the whole surface to light and then printed under a negative and developed, would not the result be a black sheet, and not even a "yellow" one? The moral is obvious.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column: but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

- I will exchange a Ross' No. 3 portrait and a Ross' No. 1 universal for a Voigtlander's No. 5 Euryscope.—Address, W. DAKIN, 1, High-street, Sheffield.
- Wanted, whole-plate view lens or lens and camera in exchange for fifty-two-inch bicycle.—Address, RIDLINTON, Photographer, Wynn-street, Birmingham.
- I will exchange a splendid interior background by Seavey, new last season, for one ditto by the same maker.—Address, E. KELLEY, 31, Old Town-street, Plymouth.
- A large artificial rock and rustic wood accessories for exchange, comprising Seavey's see-saw complete, steps, stiles, table, chair, &c. Photographs of same on application.—Address, W. W. WINTER, Derby.
- Wanted, a good whole-plate rapid doublet; exchange, magic lantern, four-inch condensers, complete in case, with comic and other slides, equal to new.—Address, COUCH, 6, Berkeley-street, Piccadilly, London, W.
- Wanted, a tricycle in exchange for the following articles:—Half-plate camera, whole-plate lens, carte rolling machine, Ross' 5x4 view lens, and other articles.—Address, MYLES GARNER, 298, Holloway-road, London, N.
- Wanted, studio camera, to take two C.-D.-V. on one plate, with extra repeating back, in exchange for Sykes's hydrometer. Difference adjusted.—Address, E. GREETHAM, Photographer, 65, London-road, Stoke-on-Trent.
- Will exchange half-plate tourist camera, swing back, rack adjustment, two fronts, and three double dark slides, book form, with carriers for quarter-plates, for 10x8 rectilinear type of lens by any good maker.—Address, J. W. C., 162, Carr-road, Sheffield.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

- G. M. J.—The shutter in question was shown by Mr. Place.
- DEVONIA.—We have heard nothing of the Company named for a long time past.
- W. E. A. D.—Better procure Mr. Wilkinson's work. It may be had through any stock dealer.
- A. H. (Montreal).—Until you see further announcements in the editorial columns, it may be well not to decide on making any change.
- J. E. HOMES.—By sheets of ebony we presume you mean ebonite. If the latter, it may be obtained from the Indiarubber, Gutta-percha, and Telegraph Works Company, Cannon-street, E.C.
- C. I. S. B.—No work devoted to the subject is published in this country. The nearest to it is Mr. Wilkinson's book, which may be obtained through any of the dealers in photographic materials. The price is five shillings.
- PORTABLE asks if any one can inform him the best photographic paper published in the French language, and the price. Also, how marks made with a copying-ink pencil on a negative can be removed without injury to the latter.
- A. C. K.—Your failure can only be accounted for by excessive under exposure. No doubt at the time the exposures were made the light was of an exceptionally non-actinic character. With more rapid plates you would probably have secured good negatives.
- I. PETERS.—The trouble arises from the emulsion being foggy—something in its preparation. Possibly it has been overcooked. The cold slab will not account for the plates fogging. If the fogging does not proceed from the emulsion then the plates must have been exposed to light.
- F. L. FISHER.—1. So far as we are aware there will be no infringement of patent if you employ the shutter.—2. Either A or B will answer the purpose better than C, if the time of exposure be an object. A lens of the smaller carte-de-visite type would perhaps cover the plate better when working with the full opening than any of the others, but either of the first two named will do very well.
- A. C. B.—You are correctly informed, and have clearly rendered yourself liable to a penalty. Section 105 of the Patent, Designs, and Trade Marks Act, 1883, enacts that "Any person who represents that any article sold by him is a patented article when no patent has been granted for the same, or describes any design or trade mark applied to any article sold by him as registered which is not so, shall be liable for every offence, on summary conviction, to a fine not exceeding five pounds."
- G. D. II.—If the gold has not been exhausted by toning it has become reduced by some means or other. It is clear that the bath was made far stronger than necessary in the first instance. Fifteen grains of gold in a toning bath of fifteen ounces is a great deal too much; such a bath, if in active condition, would be unmanageable. Your proposed plan of keeping the gold in solution and only adding it to the bath as required will be the best; but in the case of the acetate bath it should be added the day before using and not at the time.

S. W. LEFEVRE asks whether, in working up enlargements in monochrome, oil or water colour is employed, and, if the latter, what is used to make the colour flow easily?—As a rule water colour is used in finishing pictures in monochrome. If the picture be washed over with a little dilute ox-gall the colour will then take freely. Prepared ox-gall suited to the purpose may be obtained at any artists' material dealers. No difficulty need be experienced in obtaining soft vignettes, provided the mask be kept moving during the exposure. Probably the movement has hitherto not been sufficient.

HYPO writes: "For the past few years myself and assistants have taken a great number of views of buildings and other places of local interest, and had a good sale for them; lately another photographer has copied several of them and is selling the copies at a cheaper rate. We would be glad if you could let us know if we were to register them now could we take an action against the photographer for copying and against any other parties for selling them."—It is of no use whatever to register the pictures after they have been published. To secure a copyright the pictures must be registered before any copies are sold. This has often been explained in these columns of late.

E. G. RAWLINS says: "Being desirous of trying my hand at painting backgrounds in distemper and flat painting, will you kindly give me the necessary information—1. What canvas is used, where bought, and price for the large size (eight feet by eight feet).—2. How to treat the canvas.—3. What colours are employed, and what medium, or what quantities of oil and turpentine?"—In reply: 1. Unbleached sheeting, which may be had at any draper's, is usually employed.—2. A preliminary coating of common size.—3. For distemper, lampblack and whiting with sufficient size to prevent it rubbing off when dry. For flattening, the background is painted over with oil paint of the colour desired and then flatted with a similar colour mixed with turpentine only.

J. A. W. DOLLAR writes: "Will you kindly answer the following questions in your next? I have a No. 2 portable symmetrical (Ross') four-inch equivalent focus and a Watson's nine-inch rapid rectilinear lens (both cover half-plate); I want to use the single lens of either combination as a landscape lens. Should the stop be placed in front of or behind the lens (or is it a matter of indifference)? and will the single lens work as large an aperture as the combination? I should also like to combine a lens of either combination so as to produce a lens of, say, six-inch focus. Will this be rectilinear, and is it likely to cover the plate as well as the original combinations with, say, $\frac{1}{16}$?"—In using either of the components as a single lens the stop should be placed in front, that is, next the concave side of the glass. The single lens will not work with so large an aperture as the complete combination. It will have to be stopped down to $\frac{1}{16}$ or $\frac{1}{32}$, probably, to get good definition all over the plate. The lenses of the two instruments may be combined, and will, no doubt, yield good results if a sufficiently small stop be employed—possibly a much smaller one than that mentioned. The lens will still be rectilinear if the stops be rightly placed, that is, somewhat nearer the shortest focus lens than the longest.

PHOTOGRAPHIC CLUB.—Owing to the exhibition meeting of this Club taking place on January 26, 1887, the lantern night will be held next Wednesday, January 19, 1887. The discussion will be on lantern matters. Visitors are invited.

We have received from Mr. Joseph Gray, Newcastle-on-Tyne, two specimens of his new positives. They are a new departure, the credit of which is claimed by Mr. Gray. They are made by a modification of the ferrotype emulsion. When we have an opportunity to try such plates for ourselves we shall have more to say concerning them.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—We have received an attractive programme of proceedings of this Society for the next few weeks. From this we learn that the meeting of next week will be devoted largely to a display of optical apparatus of various kinds, and that ladies are invited to attend on that occasion. Proceedings are to commence at half-past seven p.m.

At a recent meeting of the Royal Microscopical Society, Mr. John Mayall, jun., exhibited and described a new form of heliostat (made by Mr. Hilger) for use in solar photomicrography. The pencil of sunlight reflected from the first mirror could, by means of the second, be directed in any desired direction, affording to the worker the very great advantage of being able to place his microscope and camera in any position he pleased.

RELIC OF THE SEA.—A photograph was washed up at Porthcawl, South Wales, and it appears to have been taken at the Park Studio, Trannemere, by Mr. W. Marshall. The photograph is of a lady, with a small child in her arms; on her right is a boy about nine years, in front of him is a little girl with a pot of flowers at her feet; on the left is another girl, leaning her head on the lady's shoulder, and having a doll in her arms. In front of her, sitting down, is a smaller boy. The photograph is lodged with the Receiver of Wrecks, Custom-house, Swansea, and no doubt on application would be given up to the family interested in the relic.

BINOCULAR CAMERAS—IMPROVEMENTS WHICH ARE NOT IMPROVEMENTS.

SOME extraordinary fallacies seem to prevail with regard to making photographs so that they shall have what is known as relief, or stand out with stereoscopic effect.

It has long been a favourite idea with some that if two pictures, taken from standpoints a few inches apart, were obtained, a stereoscopic effect would be produced by superposing these images upon one sheet of paper. We say that this has *long* been an idea. So long ago as 1853 stereoscopic views of statuary in the Louvre were projected upon a screen by a pair of lanterns in the Polytechnic Institution, one on the top of the other, so to speak, it being imagined that the resulting picture would be stereoscopic. Never was there a greater mistake. The principle of stereoscopic photography lies in there being two dissimilar views of an object, which being viewed, one by each eye, are brought into coalescence by the brain of the observer.

We are led to make these remarks in consequence of a specification of a patent which we published last week, and which will be found on page 26. The principle of the invention there patented consists in blending together on a negative the two images obtained by the employment of a binocular camera. This is effected by a variety of methods, one of which is to bend the rays to a centre common to both lenses by prisms placed behind them. But whatever be the means employed, it is the principle to which we now direct attention. We need not go very deeply even into principles, a single application will suffice. Let us suppose the subject to be a portrait, in which the nose and ears are seen, and that this portrait is taken by a binocular camera, as described in the patent. In one of the images the ear will be at a greater distance from the nose than in the other. Now on what principle are these two dissimilar pictures to be superposed? If the points of the noses be made to coalesce, then shall we have two ears at either side, one situated a slight distance from the other? or if the ears or ear be combined, then shall we have two noses? This applies also to landscapes, in which we must have either a duplication of the prominent objects in the foreground or of those in the distance.

We never willingly throw cold water upon any patent, still in this case we think it will be an act of kindness to the patentees (by dissuading them from incurring expense in carrying their idea into practical shape) to say that the same, or a similar system of attempting to combine dissimilar photographs, was patented in 1865, during which year the subject was brought before the London Photographic Society, with results which it was easy to have foreseen.

The photographs at that time attempted to be produced

were, by the inventor, termed "binographs," and, like those now under consideration, were based upon a complete misapprehension, alike unsound in principle and impossible in practice. It was shown long ago that the principle of the stereoscope is the superposition and union of two images *in the brain*, and not upon a plane surface. If two images are taken which, in the brain, will unite and form an appearance of solidity, and if these are projected upon a screen, they will never produce a stereoscopic illusion; for this reason, that in looking upon the screen each eye looks upon the same, and not upon a different picture, whereas in nature each eye looks upon a different view.

We are compelled, with reference to any invention of this nature, to repeat what we said twenty-two years ago concerning the binographic invention of that period: historically, it is not new; theoretically, it is not sound; and practically, it is not good.

GELATINO-CHLORIDE PAPER.

CHAPTER II.

AMONGST risks of this class the most prominent one is the retentive nature of the gelatine film, familiar to all workers of gelatine dry plates. What matters it that gelatine is practically free from sulphur originally, if that substance, in the form of sulphide or thiosulphate of silver, be left in the film through careless washing? We all know how difficult it is, and how important, to entirely free the negative film from hypo and its compounds; how much more necessary must it be, in the interests of permanency, to remove such compounds from the delicate positive image upon paper? Then, again, we must look at the difference between a film of coagulated albumen and one of gelatine. The former, under ordinary circumstances of treatment, is about as hardy and unchangeable a substance as we can well desire; but the latter, even when heavily chrome alumed, is liable to physical changes from damp, which may seriously jeopardise the stability of the image. Still, as we have pointed out, these are questions which hinge rather upon the care and integrity of the operator than on any inherent defect in the process itself.

Before proceeding to the details of working this new paper, we may briefly describe the physical characteristics of the commercial article as we have found it. In appearance it resembles a sample of highly albumenised paper, though on closer examination it is found to be heavier both as regards the paper itself as well as the glossy surface. It is tinted of various shades in the same manner as albumenised paper, to resemble which as closely as possible has evidently been the object, and the result has been successful to a degree.

Here the physical resemblance ends, for if we immerse a strip of the paper in warm water much of the gloss disappears and the water becomes milky; the layer of sensitive emulsion is, in fact, perfectly soluble, a fact which must be constantly borne in mind, since it entirely precludes the possibility of using warm solutions either for toning or fixing, or the application of heat in drying the prints. They must, in fact, be as carefully treated while wet as a gelatine negative, and this in the eyes of many will appear as a disadvantage. From the character of the surface, too, it is clear that the practice of drying the prints between bibulous paper cannot be as freely adopted as it is with albumen paper, or if it be it must be with the utmost precaution.

Beneath the sensitive layer we find an artificial surface composed of insoluble gelatine combined with a white pigment; it is to this "facing" that the paper owes its high gloss, and not apparently to the employment of an emulsion rich in gelatine. It also contributes to the brilliancy of the image by keeping it entirely on the surface, so much so, in fact, that if a strong print be immersed in warm water until the gelatine is thoroughly dissolved only the faintest trace of the picture remains.

If we test the paper chemically by digesting it in cold water, we shall find that it contains but the merest trace of free silver—that is, silver in the soluble state, whether it be nitrate or some organic compound. It is also comparatively free from acidity, differing in both these respects very remarkably from "ready sensitised" albumenised paper, which, however, in other respects it closely resembles.

As regards the keeping quality of the gelatine paper, we are informed that it is very good. During the time we have had the opportunity of testing it, extending over several weeks, without even the precaution of storing it in an air-tight case, it has retained not only its whiteness but also its printing and toning qualities perfectly, whereas sensitised albumen paper kept under similar conditions has become discoloured and almost entirely lost the power of toning. It has, we are told, been kept for over six months, and has performed a trip from Germany to America and back without showing any deterioration. In a parcel of cut sheets which we opened a few days ago we noticed a very faint discoloration at the extreme edges, but as the edges were in contact with a brown-paper envelope it is possibly the chemical action of the latter that caused the change.

We shall next week speak of the manipulation of the new paper.

A NEW LONDON PHOTOGRAPHIC SOCIETY.

IN view of the rumoured intended dissolution of the South London Photographic Society and in light of the fact of a new North London Society having been formed, the Gallic phrase—"The King is dead: Long live the King!" is very apt to be suggested. But the venerable "South" is not yet defunct, however soon such an undesirable event may happen.

It is, however, an undoubted fact that a new North London Society has this week been formed, and under auspices which appear to be eminently favourable to great success. Myddelton Hall on Tuesday evening, and in response to an invitation which appeared in our issue of last week, was well filled by amateurs, professionals, and manufacturers, whose places of residence are situated in the northern portion of our overgrown Metropolis; the large attendance, especially taking into consideration the inclemency of the weather and the dense fog

prevailing at the time by which travelling was seriously impeded, evincing the interest felt in the movement. Particulars as to the constitution of the newly-formed Society will be found on another page, to which those interested are referred.

Many years ago a North London Society of great excellence used to meet in the same Hall, usually under the Chairmanship of Mr. George Shadbolt, our venerated predecessor in the editorial chair of this JOURNAL, although Mr. C. Woodward, F.R.S., was Honorary President. In course of time it became defunct, an event all the more remarkable when it is considered that at the time of its demise there were over a hundred names on its list of members, and its funds were in a most satisfactory condition. But, as we said last week, it died of inanition.

For many years there was no photographic society in the north side of London; but, about a year ago, a Society, purely amateur, was formed and carried on in the same Hall so well associated with photographic progress a quarter of a century ago, and, during the past year, this young Society has most ably "held the fort." Believing, however, that the time has arrived when it might be reorganized with advantage, and on a broader basis, this Society has undergone a process of entire reconstruction, in virtue of which professionals and the trade generally, as well as amateurs, form the *personnel*.

The meetings will be conducted on lines akin to those by which the other London Photographic Societies are characterised, namely, technical evenings, alternating, as far as possible, with those of a more formal nature. The social element—evinced by the features of club life indulged in during its *séances*—is to be duly recognised by the members, many of whom are well known as active members of the kindred Societies in town. The meetings take place on the first and third Tuesday in each month, by which the second and fourth Tuesdays are left disengaged for attendance at the Photographic Society of Great Britain.

WILLESDEN PAPER AND ITS APPLICATIONS IN PHOTOGRAPHY.

"WHAT is Willesden paper, and is it of any utility in photography?" is a question which has frequently been replied to in our Correspondence columns. This material, as the majority of our readers are aware, is by no means a new one, though with a view to seeing the latest applications of it, and how they may be utilised in photography, we have recently visited its manufactory.

Willesden paper, it may be explained, takes its name from the place where it is produced. In a word, it is ordinary paper treated with an ammoniacal solution of copper, which renders it waterproof. The paper generally employed for the purpose is one of a coarse and tough character, such as that made from rope; though paper of the finest quality—writing paper for example—is equally amenable to the Willesden treatment. The "paper" is made of various thicknesses, from that of ordinary writing paper to that of stout millboard, and of different widths up to fifty-four or fifty-six inches. The thicker kinds are built up of several layers of paper, as is the case with cardboard. That designated "one-ply" is one thickness only; two-ply, two; and so on—eight-ply being the thickest made. This is composed of eight thicknesses, and is about the sixteenth of an inch thick or rather more so.

In the manufacture of ordinary cardboard the different sheets of paper composing it are cemented singly one upon

another, until the requisite thickness is obtained. In the manufacture of thick Willesden paper a different plan is adopted. Thus, if a four-ply substance be desired, a couple of two-ply pieces are secured—"welded" as it is technically termed—together; and if an eight-ply, then two four-ply thicknesses are similarly dealt with. In the welding process the material is again treated with the copper solution, which further increases its waterproof character. Although Willesden paper is waterproof, in the general acceptance of the term, it is not really unaffected by moisture, inasmuch as when it is long subjected to it, it expands like ordinary paper, though to a far less extent. With this explanation of the manufacture and characteristics of the material, we shall indicate some of its applications.

One of the principal uses of the paper is as a substitute for sheet zinc, iron, or wood, for building purposes. At the works we were shown several buildings roofed with the paper, and others with both paper sides and roofs, which appeared to be perfectly weather-tight, although they had been standing for several years. For these buildings the four-ply paper was employed. We also saw some water tanks and drinking troughs for cattle which had been made for similar periods. These were simply frameworks of wood lined with the four-ply paper. A model tank was shown us; it was composed of a light wooden framework lined with a single sheet of thin paper, and had been holding water for more than a year, and was still dry on the outside. From this brief description of its uses it will be seen that there are many purposes connected with photography to which Willesden paper may be applied. For example, in the construction of a portable studio, both for the roof and sides, it would be very useful, being lighter and more easily fixed and removed than either zinc, galvanised iron, or wood; and, when the building is taken down, the paper can be rolled up and stored away, it will then occupy but little space. It can, of course, be painted, which will improve its appearance and at the same time add to its durability. It may be mentioned that the panels in the grand entrance hall of the late Exhibitions at South Kensington, on which were the large allegorical paintings, were of Willesden paper.

One purpose to which we have seen the material applied is in the construction of a drying closet for gelatine plates, and it answered admirably; while it was so light that it could easily be transferred from one room to another. It was simply a light framework of wood covered with the four-ply paper. The paper is also used as a lining for damp walls and roofs—things not unknown in some photographic studios. A very useful application of this material which we can see, is that of backing framed photographs which have to be suspended on damp walls, as is frequently the case at exhibitions. For protecting the backs of outside showcases and frames at railway stations, and other exposed situations, it ought to prove exceedingly advantageous.

Another very useful photographic application of Willesden paper is that of extemporising vessels for water or solutions, when travelling in foreign parts or in out-of-the-way places. A common packing case, or box, can in a few minutes be converted into a serviceable water tank by lining it with a piece of the paper simply folded to shape. When such an extemporised tank has been soaked for a few hours, and then rinsed out, it may, we are assured, be used for containing water for drinking purposes. Hence, after similar treatment, it may assumably be employed for water for all photographic requirements. A sheet of the paper folded as a tray, with the corners

held together with American clips, may be extemporised as a developing or fixing dish for negatives *en route*. It may also be employed as an economical means of constructing photographic trays of a more durable kind. For this purpose the four or eight-ply variety should be chosen, and, to facilitate the bending, the paper should be previously soaked for an hour or two in water, because if the thicker kinds be bent at a sharp angle when perfectly dry they are liable to crack, but not so after moistening. In this application the corners should be secured with marine glue, and if the vessels be coated on the inside with shellac varnish, or Brunswick black, they may be used for silver solutions. Indeed, one of the most—out of the many—useful applications of Willesden paper in photography, is the case with which vessels, say of out-of-the-way sizes, which may only be required on one or two special occasions, may be constructed.

A NOTE in the *Chemical News* by Dr. Levoir, of Delft, describes a modification of the mixed-air gas-burner, which he states to have the advantage of diminished height compared with ordinary forms, besides providing for better admixture of air than usual. He makes the gas outlet conical in form, and very thin and sharp, so adopting Gifford's principle. He explains the objectionable luminosity to be seen in ordinary combustion furnace lamps as being due to the current of gas following one side of the tube, and passing unmixed with air, as a ribbon, through the tube. He, however, admits that his new lamps are not quiet during action, as when burning they make a noise like some forms of burners by another maker whose name he quotes.

It is not generally known that the manufacture of bichromate of potash was the outcome of a process of dyeing, and a very interesting account of its introduction will be found in *The Life and Labours of John Mercer, F.R.S.*, who has been called the Palissy of calico-printing. It is one of the standard quotations of the photographic historian that in the early days of photography "hypo" cost as much per ounce as it now does per hundredweight, and the same may almost be said of bichromate of potash, for when the late chemist above referred to introduced the use of chromium into dyeing, the price of the salt was half-a-guinea an ounce; but the requirements of the new dyeing operations caused a demand to spring up, and the salt is produced in hundreds of tons, and at a price which is well known to all our readers.

A WRITER in the *English Mechanic* states that the addition of ordinary kitchen salt is a great advantage to the usual oxygen mixture, as it enables the evolution of the gas to be controlled with the utmost nicety. As is well known, some experience is required in making gas in the ordinary way, in order to avoid sudden rushes or as sudden stoppages, in the emission of the oxygen. The writer in question gives the proportions (by weight), eight parts of chlorate of potash, two of ordinary black oxide of manganese, and one and a half of kitchen salt, the whole being well mixed, as being suitable, and says that the gas ceases to come off the moment the source of heat is removed, or lessens in quantity as the applied heat is reduced in degree.

THE scientific papers a little while ago had a good deal to say about the wonderful new chemical, *saccharine*, which was the latest scientific novelty of the time. It was said to have a sweetening power two hundred and fifty times greater than that of ordinary cane sugar, and fears were expressed lest glucose sweetened with this new agent should oust the genuine products of the cane or the beet from the market. For photographic purposes there would be a marvellous difference between the actions of the two. There would appear, however, to be little fear of the contingency occurring, for, according to the *Moniteur Scientifique*, Dr. Von Lippman admits that the flavour of the new sweetener is sometimes unpleasant, a sure safeguard against its fraudulent employment.

WE have often referred to the use of the hygrometer in the photographer's workrooms, and we cannot but think that when it is in daily use, and its indications taken note of, many valuable hints might be given by its aid. The ordinary wet and dry bulb instrument, however, finds little favour in the studio or laboratory, probably because it needs a little occasional cleaning. We may, therefore, call attention to a description that has been published of a new instrument for indicating hygrometric conditions and registering these indications. The acting agent in the new machine—for such, indeed, it must be called—is a film of gelatine spread thinly upon a piece of cardboard, coated at the back with asphalt to preserve it from the action of the atmosphere. The inventor has four paper spirals so coated, and attached to them various arrangements for showing the motion of the spiral as it curled or uncurled as the gelatine absorbed or parted with moisture. The apparatus registers automatically these motions, and so enables any one to tell the state of the atmosphere at any particular moment, or at any previous date. It is further stated that a model has been constructed at such a low price as to place it within the reach of all.

As the use of electricity continues to spread in photographic operations, it may be as well to draw the attention of readers to an event that happened outside a shop in Holborn a little while ago, and which if it had taken place in a photographer's studio might have led to a catastrophe. It was simply owing to the electric wire being covered with inflammable materials; the latter had caught fire, and flames a foot long were produced and continued to be for several minutes.

IN our remarks upon studio fog last week, we did not dwell upon the very remarkable exemption from its ill effects enjoyed by those who use the electric light for portraiture, a fact exemplifying to the full the correctness of our suggestions. These were, it may be remembered, to isolate the fog-laden space between lens and sitter from all action of light, and so reduce the action of the fog to the effect of a mere reducing screen instead of a light reflector. Now, in illuminating a sitter by the rays from the electric lamp or reflector they are only directed across a portion of atmosphere of very narrow section, the rest of the space between sitter and lens not necessarily receiving the slightest amount of light beyond the small portion reflected from the sitter and his immediate surroundings. This power of being able to take a presentable negative during a deep fog is one very important point in favour of the introduction of electricity in the studio.

MR. EDWARD M. NELSON in the *English Mechanic*, a little while ago, gave a description of an ingenious plan for ascertaining the components of a cemented object glass without taking it to pieces. Although the method was, in the main, intended to apply to lenses for microscopic purposes, the article gives many hints that might be of interest to photographers. We can scarcely give the account in full in our pages, but we may say, in brief, that it consists in observing the various reflections to be seen in every lens (compound or single) when minutely and carefully examined. Starting from a single biconvex lens, examined near a window, he points out that a large erect and a small inverted image of the window will be seen, the former being the reflection from the front and the latter from the back of the lens. With a plano-convex—convex side to the window—we have a small erect image from the convex side and a large inverted one from the plane side. With the plane side to the window the plane side reflects a large erect image, and the convex a small inverted one, and so on. So much for introductory explanation, which is then followed by pointing out that the cemented surface, even, throws a very faint image, generally bluish, though sometimes reddish in tinge, easily recognised when once seen. It is evident that such a faint image ought also to be visible in a cemented photographic combination, and its presence or replacement by a more vigorous reflection, will tell, without unscrewing the lens, whether it is a cemented compound or not, and approximately the character of its curves. The greatest lesson such an examination conveys is a knowledge of the large amount of reflected light that is thrown off by the surfaces of a combination. Similar reflections may be seen from the inside of a camera completely darkened, when objects of

even slight brightness face the anterior surface of the lens. When these reflections reach a certain intensity they inevitably produce fog—hence the desirability, and, indeed, the necessity, where the highest results are required, of a screen outside the lens to prevent the entry and reflection of external objects in the form of a slightly illuminated and, necessarily, fog-producing area. These reflections, limited to a given area, aid in producing the well known flare spot, and by altering the relative position of the diaphragm they are spread over the plate or concentrated on a particular spot.

Is it possible that some peculiarities of image transference in sensitised and exposed plates may be explained by a discovery published in *Comptes Rendus* to the following effect? M. P. Marguerite Delacharlouny states that liquid particles holding salts in solution are carried away with the vapour, not merely at a boiling heat but at the ordinary temperature. The same process takes place from acid salts in the solid state, such as ferrous sulphate.

THE cleaning of the windows of a studio is looked upon by many as a formidable undertaking, and, for this reason, it is often neglected for very long periods. It is not, however, a very troublesome operation if we enlist into our service an indiarubber squeegee and proceed on the following lines. If the glass be washed with clean water and a sponge, and a soft squeegee be then stroked somewhat heavily over its surface, it will at once be rendered clean and dry. Also, when it is raining, if the outside of the glass be rubbed over with a squeegee the whole of the dirt will be quickly removed without further trouble. For cleansing the outside of the glass the squeegee should, for convenience, be mounted on a long rod, like those used for cleaning the pavements.

THE SULPHURATION OF PLATINUM AND SILVER PRINTS.

I SHOULD have had no wish to enter into the controversy which has been raging for so long on the subject of the comparative permanency of prints by different processes, had it not been that Mr. Andrew Pringle's account of his experiments with bromide and platinum prints so surprised me, that I was constrained to inquire where the apparent discrepancy was to be found. Now, with the Editors' permission, and encouraged by Mr. Pringle's expressed hope that others would follow him and point out if he had been misled, I trust, without diving deeply into the question of permanence, to show how his experiments, carefully conducted though they were, have led him to a false conclusion, and how they bear somewhat unfairly upon the platinum print.

With regard to permanence, I may say that I look upon it as a purely comparative term, and agree with Mr. Pringle that to secure *absolute* permanency the image and support must be permanent alike. That being so, in any consideration of the comparative permanency of prints upon paper, by whatever process produced, the support may be left out of the calculation, being common to all; the image alone requires our attention, first, as regards its own inherent power of resisting destructive agencies, and, secondly, as the mode of its production tends more or less to bring about the destruction or discolouration of the support. In other words, a process which produces an image less easily changed or destroyed than another is more permanent, whilst the method of production which tends most in the direction of permanent discolouration of the support, immediate or gradual, by actual staining or by the formation of alterable compounds that are not removable, is distinctly less "permanent" in the strictest sense of the term. I separate the image and the support, because I think it is here that Mr. Pringle is misled.

On reading the account of his experiments, I could not help being surprised that in every case the platinum picture suffered more from contact with the solution of sulphuretted hydrogen than its fellow silver print. But upon reperusing the article, I find no mention whatever made of *fading*, but simply of "yellowing." The platinum print, says Mr. Pringle, was completely yellow, "the image side, not the back." This might, at first sight, be taken to imply that the

platinum image had faded and become yellow, and such I took it to mean; but when I remembered that the two sulphides of platinum are intensely black substances, it became evident that the yellowness could only apply to the *whites* of the picture, and therefore be due to something contained in the paper. If such should prove to be the case from an inspection of the specimens sent by Mr. Pringle to the Editors,* then, I maintain, that so far as the image is concerned there is no evidence of want of permanence in the platinum picture, nor because the bromide prints are less discoloured in the *whites* can it be asserted that the image will, for any lengthened period, resist the action of H_2S .

It becomes, then, a question entirely depending upon whether there is anything inherent in the platinotype process which renders the paper more liable to discolouration than in other processes. As I have never worked platinotype myself I am not in a position to say, but others may be; though if it should be so, the experiments only prove that platinotype prints will *discolour*, while they do not disprove that bromide prints will eventually *fade* under the action of H_2S .

Since the above was written for last week's issue I have thought more on the subject, and I fancy I can make it clear that the evidence of Mr. Pringle's experiments are distinctly in favour of the permanency of platinotype.

I am assuming, as I have already done, that the change in appearance of the platinum prints is confined to the paper, and I will further take for granted that the image itself remains wholly intact, since from an experiment with bright platinum foil sulphuretted hydrogen seems to exercise no action on the metal. The changeable substance then exists in the paper quite independently of the image, and we have to inquire what it consists of. Presuming the paper to be pure to start with, it must obviously be something used in the sensitising or development, and that something is clearly iron, for with the exception of the platinum salt nothing else is now used, I believe, but ferric oxalate and potassium oxalate. The question then presents itself, is it an absolute necessity of the process that a trace of iron should remain after every precaution for its removal has been taken? I have been assured by an experienced platinotype printer that such is not the case, but that it is quite easy with what may be called ordinary care to so thoroughly remove all traces of iron by means of the clearing solution of hydrochloric acid, that the paper will perfectly withstand the sulphuretted hydrogen test.

But supposing through carelessness in clearing the print it should retain traces of iron sufficient to cause yellowness, under the circumstances of Mr. Pringle's experiments, what is easier to remove than the discolouration? Whatever may be the composition of the colouring matter, whether it be sulphide of iron, or whether the latter, by exposure to damp and the atmosphere, be oxidised and converted into basic ferric sulphate, the result will be identical if the print be immersed in dilute hydrochloric acid or chlorine water; the stain will be discharged and copious washing will secure the removal of the soluble iron salt. The operation is, in fact, precisely on all fours with the usual practice adopted when an iron-developed bromide print is treated with dilute HCl to remove any stain, but with this additional advantage, that the platinum print will stand, without its image bleaching, an application, unlimited as regards duration or strength, and which would hopelessly ruin a silver print.

Thus sulphuretted hydrogen may be employed as a test of the removal of the iron from a platinotype without endangering the print.

Of course, if salts of other metals be employed in sensitising, as in the early process when silver and lead were combined with the platinum, there would be a possibility of traces of these remaining in the print as well as iron, and these if sulphurised—especially the silver—would be less amenable to subsequent removal, if, indeed, any means short of destruction of the paper would suffice. But I think it is clearly understood that the modern platinotype is composed of platinum pure and simple.

The principle involved in the sulphuration of a developed bromide print is essentially different from the platinotype. There is certainly

* This is precisely so; the whites are strongly discoloured, but the image itself remains intact. —Eds.

the same danger from the traces of iron left in the paper and gelatine film by the developer, but the image itself is also liable to conversion into sulphide as well as any soluble silver salts allowed to remain in consequence of imperfect washing after fixing. The yellowing arising from iron is removable, that from silver, not; indeed, the very means adopted to remove the iron stain would in time destroy the unsulphurised silver image, leaving the sulphurised portion as well as any general discolouration the most permanent parts of the picture.

Bearing this difference in view then, it is clear, as I wish to point out, that so far as the support is concerned, platinum and silver prints upon paper are both liable to discolouration under the action of sulphuretted hydrogen if the manipulations have not been carefully carried out, but that the silver print offers double risk. As concerns the image, platinum remains unchanged, while silver is liable to destruction under the same influence.

It has just struck me that even supposing (which is unlikely) that the platinum image be converted into platinum or platinic sulphide, both of which are black, and would therefore not cause any material alteration in colour, still, the permanency of the image would remain practically the same, since the sulphides behave in almost as refractory a manner to reagents as the metal itself. The former is scarcely affected by boiling mineral acids, while the latter yields only to caustic and carbonated alkalies and alkaline sulphides, none of which influences are likely to be brought to bear upon a picture under ordinary circumstances.

In accounting for the greater rapidity of discolouration of the platinum prints in Mr. Pringle's experiments, I would call attention to two circumstances, namely, the nature of the substance sulphurised and the character of the surface of the picture in the separate cases. The compound of iron in an extremely fine state of division would, I should judge, though I will not say so definitely, discolour under any circumstances more rapidly than metallic silver under similar conditions of fineness. But when it is borne in mind that the platinum image, as well as its impurities, are held merely on the surface or in the interstices of the paper support, while the particles of silver are surrounded by a skin of hardened gelatine, it will be seen that the chances of rapid change are vastly in favour of the former, and that the effect in that case would reach its maximum in a comparatively short time.

In conclusion, I think Mr. Pringle's experiments are of extreme value in calling attention to a possible, though not dangerous, cause of discolouration in connection with platinum prints; but I scarcely think it fair to take his results as evidence of want of permanence. On the other hand, he has shown that developed prints on gelatine, when made with ordinary care, will successfully withstand such treatment as they are scarcely likely to experience in the ordinary way; and that though it would, perhaps, be too much to claim for them *absolute* permanence, we may at least associate them with a degree of durability never dreamt of in connection with albumen prints.

C. BECKETT LLOYD.

LANTERN EXHIBITIONS.

Was the lantern evening of the South London Photographic Society at the Society of Arts room on the 6th instant a success?

It certainly was, in many ways. The lantern was, apparently, everything that could be desired—most brilliant light, thoroughly illuminating every part of an enormous screen, with a perfection of definition seldom attained. The slides were most effectively put upon the screen without the slightest movement or hitch of any kind by one of the new systems of exhibiting with one lantern. The number of slides so passed through was not only very considerable, but they were of a far higher average of excellence than on any previous occasion.

Here, then, was every imaginable condition of success, yet it was to me, at any rate, disappointing, although extremely instructive, and I think has taught me several valuable lessons.

1. The screen was too large. In my opinion, lantern screens generally are painfully and unnecessarily large. I have always believed that one of the first canons of art was that large pictures should be viewed from a distance, and that, consequently, a totally different system of composition applies to ordinary pictures intended to be

grasped by the eye as a whole at one time, compared with those larger pictures applicable to mural decoration. Lantern slides may of course include both classes, which may be roughly divided into "panoramas" and "bits." Each class requires different treatment to render an artistic, that is, a pleasurable, effect. In a "panorama" the eye must perforce wander about the picture, and, therefore, a general sharpness of definition is desirable. In a "bit" it is quite otherwise; there is one best point of view to which the eye should be directed, from which the best general effect is obtained. Photographically, this is attained by making the point of greatest interest the sharpest; the eye then, though it frequently leaves it to ramble over the accessories, comes naturally and instinctively back to the sharper part, from which the whole picture is apparently seen at once, but really only remembered in detail.

2. The light was most brilliant, but it utterly failed to render artistically certain slides which were over dense in the shadows, while the intense brilliancy of the high lights only increased the contrast. On the other hand, the brilliancy of those slides which could have been well shown by any ordinary lantern were in no way improved or impaired by the unusual amount of light. This fully confirmed my frequently expressed opinion that there is a standard of density possible which would give equally good results with any reasonable amount of light.

3. The light was the electric light, and not pleasing for many reasons, probably from a violet tinge which it seemed to have; moreover, it was biting and cruel, and a marked example of the old proverb, "It is possible to have too much of a good thing." I do not hesitate to affirm that it is totally unfit for lantern work, that is, for ordinary lantern entertainments, for the very reason of its wonderful powers and perfection, for of course I do not pretend for a moment that its colour could be raised as a serious objection. What was most remarkable was the extraordinary prominence given to every defect. Every dust speck or spot stood out in the most painful relief, and fully confirmed the well-known axiom, "the nearer the illuminant is to a point the more perfect the definition." As in solar enlarging no stop is necessary, the sun forming its own stop, so with artificial lighting—the smaller the source the greater the sharpness.

4. That all the various processes employed were capable of yielding results that would bear even this awful ordeal, but that they were comparatively few. That collodion emulsion fully upheld the estimation I have always held of it as by far the best photographic process yet developed.

5. That colouring a good slide is *sure* to spoil it, while it can hardly improve any bad photographic slide.

6. That at least one slide was destroyed by the heat.

Generally, that while such a lantern is a splendid instrument for taking the conceit out of any one who thinks he can make a perfect slide, a far more pleasurable evening would have resulted from a screen of ten feet in diameter, with one tenth, or less, light power.

Finally, I am extremely gratified that the experiment has been made, because it is to my mind a convincing proof that a great future for photography lies in small negatives for enlargement, and also for oil lanterns with a moderate-sized disc. I have also formed the following conclusions:—

That the oil light is better than limelight, the limelight than the electric light exactly.

GEORGE SMITH.

ECHOES FROM THE SOCIETIES.

THE future importance of orthochromatic plates for almost every purpose seems to be now beyond doubt. Though originally introduced for the purpose of giving a better rendering of colour subjects, chiefly paintings, they now seem to be no less applicable to ordinary work. At the Camera Club Mr. W. K. Burton demonstrated their utility in landscape work by exhibiting prints in which the one from an orthochromatic plate gave a far better rendering of the sky and distance, in their relation to the foreground, than was the case with the ordinary plate. At a later meeting of the London and Provincial Association a similar suggestion was made in answer to a question from the box; while at the last meeting of the Philadelphia Society the applicability of these plates to photo-micrography was urged.

In this latter department few will deny the value of the ortho-

chromatic principle in connection with many different classes of subjects. I recollect, some years ago, when the resources of the photo-microscopist were very different from what they are at present, I undertook to make a series of photo-micrographs on a large scale from whole insects. The optical difficulties in this class of work are not great, but those who have tried to satisfactorily render the various shades of yellow, orange, and brown that such objects present, with the old collodion processes, wet or dry, will know what were the photographic obstacles in the way. Exposing through yellow glass was tried, but was practically useless, owing to the great length of exposure necessary. Orthochromatic gelatine plates, however, would render the whole matter one of the simplest.

In the rendering of stained tissues and organisms; too, these plates will render valuable service. Soon after the introduction of Tailler & Clayton's isochromatic plates I was shown a number of attempts at photographing bacteria by a well-known photo-microscopist; but though valuable as showing in a graphic manner the character of the organisms, they were, as photographs, considered failures. The preparations were stained, and the bacilli themselves showed transparent and nearly colourless on a blue ground, and consequently presented little contrast to the ordinary plate. I suggested the employment of the new isochromatic plate, and since then I believe my friend has done a considerable amount of good work by adopting the principle.

Mr. J. B. B. Wellington's application of the orthochromatic treatment to collodion plates is a still further extension of the principle, though it is in reality only a return to the original idea. But, as Vogel pointed out long since, the orthochromatic effect of eosines upon collodion films is many times greater than upon gelatine, or, in other words, the sensitiveness to yellow is increased very much more in a collodion plate than in one of gelatine, the increase in the former having been placed, speaking from memory, as high as sixty times. This being so, it is easy to see how, by rendering a collodion plate orthochromatic, it may be under certain conditions brought nearer to the sensitiveness of gelatine, and with such treatment I should not be surprised to find a reaction in favour of collodion for many purposes.

One application of the orthochromatic principle to collodion plates may be of interest to amateurs, especially those who make their own lantern slides. Most of these are compelled by circumstances to work in the evening and by artificial light, which is all very well if their negatives do not require reducing, and can be printed from by superposition. But if the camera has to be employed the exposure is hopelessly long—I am speaking now of collodio-bromide—hence many who would prefer to employ that process are debarred from doing so by the inconvenience in exposure. But if, by a suitable addition of eosine or erythrosine, an emulsion or plate twenty or thirty times as sensitive to yellow can be produced, we shall be getting—at any rate for artificial light—"within measurable distance" of the rapidity of gelatine, while still retaining the special qualities of collodion. Here is a field.

While the general consensus of opinion is thus decidedly in favour of orthochromatic photography, it is somewhat startling to find a man of some reputation boldly stating, as Mr. George Smith did before the Photographic Society, that he "believed orthochromatic photography to be a delusion." That such a statement should fall from Mr. Smith surprises one the more because on many points he is usually well informed; and if it be correct, then, surely, as Mr. Bolas suggested, there must exist a conspiracy of lying in scientific photographic circles.

It was a happy suggestion on the part of Mr. Valentine Blanchard to the Camera Club to make more use of plain paper for printing purposes. The tendency of late years has been strongly in favour of matt surfaces for printing, and I, for one, am surprised that so little attention has been given to the simplest of all matt-surface processes. Can it be that it is because it is an old process, one that was superseded by the present albumen method, and that to go back would be to err? Retrogression does not always imply the negation of progress; therefore, if matt surfaces be the order of the day, let us produce them by the readiest and most convenient means that will give the necessary quality of result. For artistic effect nothing can exceed in beauty well-executed prints on plain paper, and the process offers a far wider range of tones than either platinotype or gelatine. I do not want to get into hot water, so I will only add that their permanency has stood the test of many years.

I was glad to see in the report of one of the meetings of the London and Provincial a very decided expression of opinion by two members whose experience none will dispute. The question was as to the best method of photographing a white chrysanthemum against black velvet. Mr. A. L. Henderson and Mr. A. Cowan both agreed that a slow plate with sufficient exposure would give the best result. I am pleased at this, because it has been my own opinion for years; but I was astonished a few weeks ago to hear from a high authority on dry-plate matters that the more rapid a plate is the better the gradation, and the more complete the scale or gamut. I must confess that my own experience has been the reverse—that where the gamut of a slow plate rises, so to say, by tones and semitones, that of a rapid one leaps up by octaves, the intervals being indistinguishable. How often do we find a plate that will give “25” on the sensitometer that will also make a visible distinction between half-a-dozen numbers?

I should like to have heard Mr. W. Tylar's paper on *Useful Hints*, read before the Birmingham Society. I suppose the first great trial in an amateur's life is when he makes his first photographic trip to a distance from home. I know from my own experience how unavailing seem the most careful preparations, and how helpless one feels when, cut off from the “base of operations,” some important item of the kit has been left behind. I have heard of the gentleman who travelled a hundred and fifty miles to take a particular view, and finding he had left his lens at home, executed his picture with a pin-hole in a piece of card. That raised feelings of scepticism. I have seen a High Church parson gaily dancing about a populous village in his shirt sleeves, his cassock doing duty as a focussing cloth, and I wondered what his bishop would have said. I have been startled by the bad language of a young man who had left his changing box at home, and reflected on the sad consequences of youth and carelessness. But these are only outdoor troubles, and Mr. Tylar's hints, from what I can gather, refer rather to matters connected with the travelling dark room—a department generally sadly neglected by the tourist photographer, whose regrets come too late when he experiences the misery of his circumstances; for nothing to my mind is more miserable than working in an improvised dark room, with badly devised makeshift appliances. *Useful Hints* would, no doubt, show how these latter may be improved.

Speaking of improvised dark rooms reminds me of an incident that occurred once when I was staying at a farmhouse in Cumberland. My dark room was a store room under the tiles or thatch, and without a window, and my developing table the head of a barrel, which I afterwards found was the stock oatmeal cask of the family. It was in the old days of cyanide fixing, and one day I managed to send in one-half of the barrel head, and with it about three-quarters of a pint of cyanide solution into the family supply of oatmeal. Upon investigating matters, and finding there was only a small quantity of meal in the barrel, my conscience refused to allow me to run any risk, so I insisted on paying for the oatmeal and having it turned out. I learnt afterwards, however, that the canny Cumbrian, being loth to waste anything, and apparently doubting my word as to the strength of the “poison,” had given the meal to his pigs, two of which were just about to be killed. Whether the toxic effects of cyanide upon the porcine race are less marked or not than on “the human” I cannot say, but the pigs survived. I expostulated with the farmer on the risk he had run, suggesting that he would have blamed me if anything had happened. His reply was, “Naay! it wadn't ha' mattered! I'se jest gain' ta kill 'em, and it 'nd a spart t' bootcher coomin'.”

I am afraid Dr. Tulloch had taken my remarks or strictures upon his paper too much *au sérieux*. The “somewhat inane remarks” with which I commenced were intended to prepare him for a little gentle “chaff,” but apparently the surgical operation proved insufficient. However, as Dr. Tulloch says he “purposely introduced debatable matter with the express purpose of having a lively discussion,” he can scarcely blame me if I fell into the trap. Had I been aware that Dr. Tulloch expected all the arguments in a discussion to be on his side I should have let him alone.

Apròpos of the reference I made to the possible barter of cameras for meerschaum pipes, I wished to typify one class of amateur photographers whom Dr. Tulloch does not consider acquisitions to the ranks. The meerschaum pipe is the aspiration of many a lad fresh from school, especially such as find anything like photography to

overtax the brain. Hence the meerschaum pipe is a prominent figure in various “Exchange Columns.” The late J. W. Gough once advised some one to “sell his camera and buy a bicycle—he will never make a photographer;” but I have just come across an individual who has come to the latter conclusion himself, and that in a remarkably short time. In one of the papers devoted almost exclusively to sales and exchanges I encountered a few days ago, under the head of “Photography” the following, which I quote as nearly as possible verbatim, having mislaid the cutting:—

“For sale, Lancaster's Merveilleux quarter-plate camera, cost 21s. a week ago, lamp, cost 2s. 4d., and ten dry plates. Will take 20s., having given it up. Address, &c.”

The gentleman whose experience, extending over one week and involving the manipulation of *two* dry plates, has induced him to “give it up,” has at least one virtue. He has early recognised that he will not make a photographer. MONITOR.

THE TRANSFER OF COLLODIO-CHLORIDE PICTURES UPON GLASS, PORCELAIN, AND IVORY.

[Translated from the German by J. Hubert.*]

HERETO the transference of collodio-chloride pictures upon glass was attended with many difficulties while gelatine formed the support. I asked myself the question, Would it be possible to achieve this without heat? and my first experiment has been successful.

Instead of gelatinised, I take gummed paper, on account of its solubility in cold water, which greatly simplifies the manipulation. Treble gummed paper, which can be obtained commercially, is fixed into the coating frame, and to obtain a thick film the emulsion is spread slowly. I print this collodionised paper in the printing frame to such a depth that the lights assume a bluish tint, and the shadows have a deep, black appearance. The transfer may be effected directly or indirectly, so that the pictures may be reversed or otherwise at will.

For lantern slides and window pictures the first process is used, and as the simpler I will discuss it first. A glass plate is coated with a ten per cent. solution of gelatine, dried, and immersed in cold water at the same time with the deeply printed copy; take both out and press into contact with a squeegee. After a short time it will be practicable to remove the paper, and the picture will remain on the gelatinised glass, porcelain, or ivory support. Now fix, by pouring hyposulphite of soda over it; wash well, and dry.†

If it is intended to correctly represent the picture upon its final support coat this with gelatine also. A transfer paper is used, which is prepared by immersing glossy and glued paper into a solution of ether copal varnish. This paper is dipped with the copied pictures into water, both are taken out, and the picture laid upon a slightly larger glass plate. Now squeegee, remove the gummed paper, fix and wash. Finally lay the picture upon the gelatinised surface, squeegee again, and remove the transfer paper. To reproduce negatives which are quite equal to the original, all that is necessary is to make a positive after the first method and from this a negative after the second method. LIESEGANG.

CAN PHOTOGRAPHY LIE?‡

HAVING just received a message immediately to come round to a neighbour's house to photograph the dead body of a little girl, and as there are no more sitters in waiting, I undertake the task myself, though I confess my preference for bodies that have as yet not made acquaintance with the unknown multitude that undoubtedly have found that zenith of glory which we that are left behind vainly seek in this vale of hope forlorn. Having examined the certificate of death, to guard myself from any such disasters as catching the measles or whooping cough, or transferring the same undesirable maladies to my customers, I proceed to the chamber where the shadow of death hath cast its awful gloom, and where every aspect seems to bear an imprint of *memento mori*, while the heart is uplifted in silent prayer. Here, in the hallowed and mysterious presence of the sweet little innocent, it is indeed difficult to follow mercenary pursuits. Sympathetic chords, in tender melodies, compel me to persuade the bereaved parents not to carry their intention to perpetuate the sad scene further. Nothing avails, however. It must be done. I cause the child to be placed near the centre of the room, whilst I positioned my camera in the corner opposite, nearest to the window, so as to form a right angle. Having arranged the blankets in such a manner as would form a little bed, I altered the position of the

* See Report of London and Provincial Photographic Association.

† In my own experiments I have previously toned the pictures on their support and succeeded well.—*Translator*.

‡ Concluded from page 25.

Venetian blinds so as to throw a decided but soft shade on to the face to form the merest point of high light, and employing a plate possessed of the finest gradations of half tones, exposed for the shadows. I only use a reflector in case I am compelled to place the corpse very near the window; but as time of exposure is no criterion, it is always best to use the middle of the room to obtain the softest picture. With regard to position, I take the greatest care not to show the nostrils. I have in this way always managed to produce pictures which were more sleep than deathlike. Here are some of the results. It adds another to the chapter of lies; but who can blame the perpetrator? ought he not rather to be blamed if he revealed the horrible truth, which with every fond look would tear open the wound of despair, which by the other means has passed into the healing state of resignation?

I arrive home just in time to save my assistant from being torn to pieces by a dog sitter, whose animosity he has roused by indelicately representing himself to be a cat, which contingency the owner had evidently not foreseen when he left operator and sitter alone in the studio. Master Felix being secured by the camera and by the owner, my services are called into requisition by the present guardian of a little lunatic, whose growing tendencies to that state of existence had made it appear desirable to remove him to more appropriate lodgings.

To photograph such an object was rather novel to me, though the guardian was sure that I could represent the poor thing as a perfectly rational being. Now I was just becoming conscious that photographers did occasionally resort to a lie, but here it was forcibly brought home to me that they have a reputation for that malpractice. How dreadful! The lunatic, who probably taking a fancy to me, had embraced one of my legs so tightly that I was divided in my perplexity whether to photograph or to get rid of him. I was, however, not to be in doubt long, for releasing my *pedes*, he seemed to think it fine fun to mount my camera stand and look into the box, as he was pleased to call it.

To describe his antics would be impossible; they were many and varied. Suffice it to say that he nearly drove me to the same fate which so unfortunately had overtaken him before I had succeeded to make an impression upon him and the plate. This state into which I had thus worked myself could not have been more unfortunate, for I had to photograph a lady next who was subject to fits, the uncertain recurrence of which at any moment might be looked for with tolerable certainty, especially under such an ordeal as photograph taking. My unfitting state at such a moment did not seem a fitting occasion to fit the camera into position without causing the fit to be communicated to the subject of fits, but I managed it. You may ask, Mr. Chairman and gentlemen, what this sitter can possibly have to do with my subject. Well, I should certainly not have thought it fitting to mention the matter here had she not been subject to St. Vitus dance as well, and as undoubtedly you will agree with me that photography as yet is not capable to reproduce this amusement truthfully, it must be a lie. If you should, however, think this statement far-fetched, and some of you gentlemen are burning to open a discussion thereon, I feel compelled to name this part as not for discussion, and proceed with lying matters more truthfully narrated. This you may think an easy matter, but it is not such for me, so, as you will probably be getting tired of my paper, I will try to get out of the difficulty by drawing the matter to a conclusion, before my whole day's work has been accomplished. This will be a pity, I assure you, because you lose the best part of it; but there being no rose without thorns, and in England not many days without rain, we must try to make the best of matters. At any rate I was obliged to do so, for a group of forty bicyclists had just arrived, while the heavens began pouring forth their resources of condensed moisture in such liberal quantities that the spirits of my intended sitters were so diluted as to be quite unfit for immediate consumption under the coming ordeal. I received, however, material help in keeping them up from a member of the company, whose exclusive right to joke at the expense of all, myself included, seemed unquestioned, nor would it have been at all within the reach of probabilities that if requested to give some one else an opportunity to speak he would have accorded that facility. His flow of language came to an end, but the rain would not follow suit, and as by this time the next important member—whose cardinal virtues did not include patience—had affected several of his comrades, some of which had already expressed a desire to ride off; an altercation ensued, which ended in the departure of their master of ceremonies. He being out of sight it became evident that that man had been the obstacle, for Master Sol burst out from among the clouds, greeting us with one of his most sarcastic smiles, and withdrew again; but whatever other tricks he might have served us Mr. Wind prevented them, and bracing himself up majestically blew away the clouds that had been despatched by the deceitful luminary. I took the opportunity, and prepared for action. Some little time was occupied in persuading the company to sacrifice the master of ceremonies, but eventually the matter was compromised by my conditional promise to introduce him into the picture afterwards. As this was only promise I hoped to evade the perpetration of this lie, but being fully prepared to do it if necessary I left room for the picture in the middle, which place I chose in preference to make the difference not too striking, as the corners not being always so sharply in focus, would hardly agree with a well-defined studio picture.

To arrange a large group quickly, and obtain at the same time good expressions of most, is a matter of difficulty. It requires influence and

power to impart to the company the knowledge that you are fully master of the situation. The only way to grapple with large numbers is to place part on the ground, avoiding, of course, showing the soles of the feet, part sitting behind on low forms, part standing behind these, the next part standing upon forms, and the last part standing upon tables or double row of forms. The loan of these forms from the nearest school has never been refused to me, and in this case I used them in the manner indicated. I gave each man a number, which is the best way to convey to them quickly and effectually where to look and how to hold the head. I finish up with a few words, telling the company how to avoid the usual meaningless expression, entreating them to remain steady, as otherwise my expensive plates would be wasted, besides courting certain failure, and losing time and temper. I had just readjusted the cap of my lens when a peal of thunder and simultaneous shower of rain put an end to my outdoor operations, the shock being so sudden and severe it disconcerted me so that the very recollection of it now brings my paper to a very desirable conclusion. Gentlemen, real thunder is a terrible thing; it cannot be compared to the thunder of displeasure you may shower upon me. The atmospheric disturbance accompanying the phenomena has always had special influence upon the photographer and his materials. Look upon the qualities of the dry plate makers, thunder, weather productions; these lend themselves seldom to the conditions discussed in my paper, in which I have attempted to show what you all know, that photography can lie.

But I cannot agree with a member's remark of two weeks ago that this paper should have been entitled, "Can Photography tell the Truth?" I think it safer to leave that to the proposer to demonstrate. I can picture to myself the indignation of the fair sex, the horror of the swell, the revolt of old maids, and similar disasters, at the mere hint of a doubt of photography being able to tell the truth. I should recoil from the consequences of such an indiscretion, and it must indeed be a bold man to venture upon the task, which, as it stands, is almost too difficult to treat in a serious manner. I trust indeed, gentlemen, that you will therefore excuse my frivolity. I will finish in a more dignified way. As you are all aware, photography can be used at will for any purpose. By different treatment in the process, by the use of lenses of different construction, by including different angles, by negative and positive retouching, by each and all these means we can, in a more or less degree, describe an object truthfully or inaccurately. If Mr. Jack, the plaintiff, exhorts you to represent the house he built by dimensions especially suited for the purposes of making out his particular case before the Lord Chief Justice, you can satisfy the demand, and you can have it equally in your power to be as obliging if Adam, the defendant, has recourse to your services. How to wield the power you possess is the point. If you are not careful the judge may call you a humbug, if he is so disposed, and if you are over careful you may lose your clients. But take what course you will, let me entreat you not to follow the abominable practice of retouching away all likeness of a person you may wish to beautify. Strive to represent everything and everybody to the very best advantage. If you go as far as making a mule out of a donkey, do not conjure up a horse from the original carcass of the intelligent ass. The great majority of your sitters will be satisfied if you soften the wrinkles of old age, take away freckles, conceal the loss of an eye or a leg, and prevent solarisation of a hairless crown. Those that are not you may safely disregard, and count amongst the number of enemies which you are sure to create if you succeed in this life; and that this may be the lot of all that are assembled here is the earnest and sincere wish of your humble servant,

J. HUBERT.

THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

THE following circular has been issued:—"The success attending the Inaugural Meeting of the First British Photographic Convention, held at Derby in August last, has been duly recognised, and fully commented upon by all the leading English and American photographic and scientific journals. It has been decided by the Executive Committee that the Convention next year shall take place at Glasgow on Monday, July 1, and extend over one week. The hearty co-operation of the Glasgow Photographic Societies has been assured. Of the advantages of an annual meeting of this kind it is unnecessary here to speak, affording, as it does, the opportunity of an agreeable and profitable interchange of experiences, and a pleasant reunion of all ranks of professional and amateur photographers.

"The arrangements will take the following form:—Excursions with the camera daily, to places of interest in the neighbourhood, either by coach, rail, or other conveyance, under the direction of specially appointed leaders. The evenings will be principally set apart for the reading of papers, demonstrations, exhibition of apparatus and mounted prints, in addition to selections of transparencies, which will be shown with the oxyhydrogen optical lantern. A detailed programme of time of meeting and all other particulars will be forwarded to each member as soon as final arrangements are complete.

"The subscription will remain at 5s., it having been found sufficient to cover all general expenses incurred at the last meeting.

"Members who wish to contribute papers, or to become exhibitors, should forward their names at once, with the space they wish reserved, in order to facilitate arrangements and prevent disappointment: a form on the fly-leaf hereof will be found for that purpose.

"I shall be glad to add your name to the list of members, and to secure your support for a movement that must commend itself to every one interested in the art-science of Photography.

"J. J. BRIGNSHAW, Hon. Sec.

"21, Albert-road, Walthamstow, December, 1886.

"Communications may be addressed to the Local Secretary, James Davie, 36, Darnley-street, Pollokshields, Glasgow."

We append the list of the Members of Council, which was inadvertently omitted to be given among the announcements of Societies in our ALMANAC:—R. Bolden, *Derby*; F. A. Bridge, *London*; W. K. Burton, *London*; W. Cobb, *Woolwich*; A. Cowan, *London*; J. C. Cox, *Lochie*; J. Crosby, *Rotherham*; W. England, *London*; W. Forgan, *Edinburgh*; A. Hadden, *Greenwich*; W. Jerome Harrison, *Birmingham*; A. I. Henderson, *London*; J. Henderson, *Perth*; H. Keene, *Derby*; W. Lang, jun., *Glasgow*; Rev. Victor Macdonald, *Cheadle*; A. Mackie, *London*; G. Mason, *Glasgow*; S. D. McKellen, *Manchester*; W. H. Prestwich, *London*; A. Pringle, *Langholm*; H. P. Robinson, *Tunbridge Wells*; J. Stuart, *Glasgow*; J. Traill Taylor, *London*; C. H. Trinks, *London*; J. Tunny, *Edinburgh*; R. Turnbull, *Glasgow*; J. M. Turnbull, *Edinburgh*; W. D. Valentine, *Dundee*; J. B. B. Wellington, *London*; G. W. Wilson, *Aberdeen*. There is, in addition, a large local committee.

The local Committee held their first meeting at the Religious Institution Rooms, Glasgow, on Thursday night, the 13th instant.

On the proposal of Mr. Mason, seconded by Mr. William Lang, jun., Mr. John Stuart was unanimously elected Chairman of the local Committee.

The local Secretary reported that ninety-eight gentlemen had been nominated as members of the local Committee by the Glasgow members of the Executive, in pursuance of the power accorded to them by the meeting of Council held in London on October 14 last, and that, by the number who had intimated acceptance of the appointment, the local Committee consisted of seventy members, forty-two professional and twenty-eight amateur.

The Chairman explained fully the purpose of the Convention, and pledged himself to do all that lay in his power to make the Convention of 1887 a notable success. He called upon the members of Committee to make such preparations and arrangements as would insure the comfort of, and give pleasure to, the visitors and friends who would come from all parts of the United Kingdom to the Convention meeting at Glasgow in July.

The heartiness with which the Chairman's remarks were received showed that the members of Committee were quite prepared to give a cordial welcome to all the friends who might come.

The Chairman proposed the names of members to form four sub-committees to undertake the necessary labours. These sub-committees to be called, *Reception Committee*, *Exhibition Committee*, *Excursion Committee*, and *Entertainment Committee*.

The Chairman's proposals were adopted by the meeting.

The local Secretary was directed to correspond with the Scotch Societies, and invite their co-operation and assistance.

REORGANIZATION OF THE NORTH LONDON AMATEUR PHOTOGRAPHIC ASSOCIATION.

A NUMEROUSLY attended meeting was held on Tuesday, the 18th instant, at Myddelton Hall, Islington, for the purpose of taking into consideration the advisability of reorganizing the above Society and establishing it on a broader basis.

Mr. J. Traill Taylor, having been unanimously voted to the chair, called upon Mr. H. M. Smith, the Hon. Secretary of the Association, to read the letter convening the meeting.

On the motion of Mr. J. Humphries, seconded by Mr. F. W. Cox, it was resolved to reorganize the Association under the title of the North London Photographic Society.

The proposed rules of the new Society were then read, and after an animated discussion, in which a considerable number of gentlemen, including Messrs. Clifton, Cox, Coventon, Few, Hiscock, Mackie, Medland, Oakley, Spencer, G. Smith, H. M. Smith, and the Chairman took part, were, after sundry modifications, agreed to.

The principle features in the reorganized Society are briefly as follows:—

An annual subscription of 10s. Bi-monthly meetings on the first and third Tuesday in each month. The Society to be open to both professional and amateur photographers. The points arising in the everyday practice of photography to be discussed in preference to the more abstruse questions which are so fully dealt with by the older Societies, with a view

to making this Society, as far as possible, a practical school of photography.

The following gentlemen were elected as officers:—*President*: J. Traill Taylor. *Vice-Presidents*: Alexander Mackie, J. Humphries. *Curator*: E. T. Hiscock. *Council*: Edgar Clifton, F. W. Cox, W. T. Coventon, W. Few, L. Medland, J. Oakley, F. G. Reader, Geo. Smith. *Hon. Secretary and Treasurer*: Hedley M. Smith, 5, Beatrice-road, Stroud Green, N.

The Hon. Secretary will be glad to receive the names of gentlemen wishing to join the Society. Demonstrations and papers for several meetings have already been promised. The next meeting will take place at Myddelton Hall, Upper-street, Islington, at eight o'clock on Tuesday, February 1. Visitors are invited.

Department for Experienced Photographers.

DEVELOPMENT BY PYROGALLIC ACID.

LAST week we described the method of development by means of ferrons oxalate.

Previous to speaking of the effects of under or over exposure, and the means by which such can be discovered, and in some measure rectified, we shall give an account of development by the agency of pyrogallie acid.

The method now to be described is one of several hundred different systems of development employed, for nearly every worker, while giving general adherence to a formula, appears to make some slight departure from its strict letter in order to suit his own special requirement. But pyrogallie development is all based upon one foundation, namely, pyrogallie acid dissolved in water together with an alkali. As regards the latter some prefer ammonia, others one or other of the fixed alkalies, carbonate of potash, carbonate of soda, or carbonate of ammonia, or sometimes a mixture of two or more of these.

At this stage we do not wish to hamper the mind of the beginner by presenting to him a number of formulae, but shall content ourselves by giving him such simple directions by which to develop a negative as will render it well-nigh impossible for him to fail.

In a bottle or vessel of any kind—a glass tumbler, for example—place a dessert-spoonful of common washing soda, previously crushed, and to this add a quantity of water not quite sufficient to dissolve it all. If it does, add more soda till the water will dissolve no more. In another vessel do precisely the same, but substituting carbonate of potash for the soda salt. Now take a bottle having turnover lip and a nicely fitting cork, and pour into it equal quantities of the two saturated solutions described, and for each ounce of this mixture, whatever the quantity may be, add about four drops of strong liquid ammonia. You have now a stock alkaline solution which is always ready for use, and will last a long time, as it has to be used very sparingly. The vessels in which the solutions were prepared may now be washed out.

Just before developing, and having guessed the quantity of water necessary to cover a plate when lying in the developing dish, and which may be one, two, or three ounces according to the size of the plate, dissolve in this quantity of water pyrogallie acid in the proportion of two grains to each ounce. Having placed the plate in the dish, face up, pour over it the pyrogallie solution, taking care that it is made to flow over and wet the surface thoroughly, thereby avoiding air bubbles, which would show eventually as white spots on the negative.

Having allowed the pyrogallie solution to act on the plate for about half a minute or more, it is then poured off into a graduate or other suitable vessel, such as a porcelain egg-cup, into which two drops of the alkaline solution have been previously dropped from the stock bottle. This alkaline pyro solution is again poured over the surface of the plate, and a sharp look-out kept for the appearing of the image. Do not get flurried or impatient should the image be slow in appearing: it is bound to come. Still, should an unusually long time, say two minutes, elapse without the image coming, it may be necessary to add one or two drops more of the alkaline solution; but it is wise to do this with care, for if too much were added, the negative might develop with an unmanageable degree of rapidity.

After the details are all well out, let the development be continued until they seem to disappear, leaving nothing but the very deepest shadows white. After this remove the negative, wash it slightly under a tap, and transfer to the hyposulphite of soda fixing bath made in accordance with previous directions.

We shall next week speak of over and under exposure, and how to discover and ameliorate these.

PATENTS COMPLETED.

IMPROVEMENTS IN PHOTOGRAPHIC SHUTTERS.

No. 2384. CHARLES DAY DURNFORD, Ordnance Store Department, Edinburgh.—*February 18, 1886.*

THE object of my invention is to produce a shutter for use with photographic cameras, which can be used either as an instantaneous shutter or for longer exposures, as may be desired, or for the production of double exposures, that is to say, exposures producing the effect of the use of stops or diaphragms of different sizes during practically the same exposures, by the which may be obtained the minute definition of the small stop with the brilliancy and softness of the large stop.

This shutter is preferably used between the lenses when a double combination lens is used, but several of its component parts are adapted for use when the shutter is fitted in front of, or behind, the lenses. With this shutter the ordinary stops or diaphragms may be used; these stops and the slide, or drop, of the shutter being preferably placed in as close a juxtaposition as is possible.

This shutter is similar in its action, and somewhat similar in its construction, to an ordinary drop shutter, but the rapidity of the drop is preferably increased as may be desired by the action of a wire or other suitable spring, one end of which is secured to a pivot placed in a light-tight casing at, or near, the side of the lens tube, while the other end passes through a slot in the lens tube to a staple or other appliance in the drop or slide, and through the same, so that, when this spring is in tension, the drop or slide is forced downwards at a quicker speed. This arrangement is similar to that described more fully in the specification filed in pursuance of my application for a Patent, dated the 15th of September, 1885, and numbered 10,896. Another method of fitting this spring consists in mounting the pivot thereof on an arm or other projection fitted on the frame of the shutter or on the lens tube, or elsewhere, while the other end of the spring is connected to, or held by, or on the top edge of, the slide or drop, which is always outside the lens tube, preferably in such a manner that this end of the spring can be disconnected therefrom when not required. When the spring is connected or attached to drop or slide, the tension thereof, and the consequent rapidity of motion, can be regulated by a lever attached to the pivot of the spring, by which the same can be turned, and when required, held in position by a ratchet rack, as is more fully described in my said specification, No. 10,896 of 1885, or the tension thereof may be regulated by attaching a chain to the end of the lever, and hooking the desired link of this chain on a pin, or jamming the chain between two pins on the frame of the shutter, or elsewhere, or the tension may be regulated by any other usual devices.

The slide or drop, and the aperture or apertures therein, may be of any desired shapes and sizes. When a double exposure is desired, a narrow vertical slot may be made towards the lower part of the slide, which slot at its upper end opens into an upper and larger aperture, preferably of the same size as, or a little larger than, the largest stop or diaphragm that is to be used, or two separate apertures may be made, of which the smaller is the lower one. Suitable recesses or notches are made in the sides of the slide or drop in the proper positions to receive one of the two catches that are connected together, or formed in one piece so as to create a double catch, which is actuated in any convenient manner, preferably by the usual tube and collapsible ball acting on a pneumatic piston in a tube. This double catch preferably consists of a wire or rod, which moves freely across the front or back of the drop or slide, preferably just above the lens tube, on which are formed, or to which are attached, the two catches, so situated that they cannot be both engaged in the notches or recesses in the drop or slide at one and the same time. When one catch is engaged in the lower notch or recess, the slide closes the aperture in the position required before exposure, and when this catch is retired, the slide or drop falls until the other catch engages in the second notch, preferably on the other side of the slide or drop. In this position the light is admitted through the narrow slot or smaller aperture, and when this exposure is finished, the second catch can be retired, when the slide or drop falls home, thus allowing a rapid flash of light through the upper or larger opening, and again closing the aperture, or the notches may be so placed that the first catch holds the drop or slide in position to admit light through the narrow slot or lower aperture, and the second catch holds the same to admit light through the upper or larger opening, or a third notch may be added to combine both these arrangements, or otherwise.

When only an instantaneous exposure is required, a stop can be applied to the double catch, so as to permit the release of the first catch, but prevent the advance of the second catch sufficiently far to engage the other notch.

IMPROVEMENTS IN HOLDERS OR CARRIERS FOR FLEXIBLE MATERIAL SENSITIVE TO LIGHT, FOR THE PURPOSE OF TAKING PHOTOGRAPHIC PICTURES.

No. 2390. FELIX JOSEPH VERRARA, Lordship-lane, Dulwich, Surrey.
February 18, 1886.

THIS invention relates to dark slides, or apparatus for holding and carrying surfaces sensitive to light, which are exposed in an ordinary camera for the purpose of obtaining photographic pictures in the usual well-known way.

It has for its object a novel method of constructing and arranging such holders or carriers so that they can be conveniently applied to the purpose of holding sensitive sheets, or films of flexible material, such as paper suitably prepared and made sensitive, instead of sensitised glass plates as ordinarily used.

My improved film holder consists of a frame or slide of cardboard, ebonite, wood, or other sufficiently light and strong material, two opposite edges of which are provided with grooves or guides fitting upon corresponding guides upon the back of the camera with which it is to be used, and the guides are so arranged that the slide can be inverted when desired, so that either side can be adjusted next to the camera.

At the outer end of the slide is a central vertical groove, into which slides a central plate of cardboard, wood, or other suitable material; and the groove is sufficiently wide to allow two thicknesses of the flexible sensitive film which is to be used to pass freely through it as well as the central plate.

Upon each side of the central groove is made another narrow parallel vertical groove, into which are fitted two opaque sliding shutters, which may also be made of cardboard or other materials, as already described.

These side grooves, and the shutters which slide in them, are separated from the central groove by thin sheets or flanges of similar material, having openings through them corresponding with the openings in the slide, which determine the size of the picture upon the sensitive film.

In order to prepare the holder or carrier for use, I withdraw the central slide, and I take a sheet of the sensitive film of such length as to somewhat more than cover both sides of the slide, and I fit it upon the latter by folding it transversely at the centre of its length over the end of the slide, and I then introduce the latter, together with the fold of the film, into the central groove, and I push the slide into its place, the film being stretched and held steadily upon each side of it.

The two shutters being also pushed forward in their grooves upon each side of the central slide until closed, the entire holder can be fitted in its place at the back of the camera, and the part of the film upon one side of the central slide exposed, the corresponding shutter having been first opened.

When the picture has been taken and the shutter closed, the holder can then be inverted so that a second picture can be taken upon the other part of the film upon the opposite side of the central slide.

The slide or holder made and used in the way described is very simply and cheaply made, light, and easily used; and as each holder contains sufficient sensitive film to take two pictures, a considerable number of pictures may be obtained with a moderate number of holders of comparative little weight, and this method of using flexible sensitive film is more convenient, and requires far less trouble and care of adjustment, whilst it gives greater certainty of result than in forms of arrangement in which a large number of pictures are taken upon a single film of great length which has to be adjusted and rearranged after each picture has been obtained.

The improved holder may be made of cardboard, cemented together in sheets of the required thickness to form the several grooves and flanges, proper openings being made through them where necessary, and in this form it is very light and cheap; or it may be made of ebonite or of wood, especially where large-sized pictures are to be taken.

Suitable stops may be arranged upon the shutters to limit their movement, and the openings through which they pass may be made sufficiently impervious to light in the usual understood way; and tongues or handles are provided upon the shutter and slides for their manipulation.

I make the central slide preferably slightly taper in width, so that it may more readily be introduced, together with the folded film, into its groove, and the ends of the latter may be left slightly protruding when the slide is in its place, so that they may be easily withdrawn with the latter.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

ON Thursday night, January 13, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. Alfred H. Harman presided.

MR. A. COWAN asked if Mr. Wellington's orthochromatic emulsion would not have worked even better had he left out the iodide.

MR. J. B. B. WELLINGTON had not tried the experiment.

MR. A. L. HENDERSON said that Mr. Hyslop had told him that in making plates orthochromatic he could use ammonia with colouring matters yet develop without any fog at all, and omitting the intermediate use of a bromide of potassium bath.

THE CHAIRMAN thought that unless orthochromatic plates would keep well they were not of great commercial value.

MR. WELLINGTON said that recently he had made some plates with erythrosine and silver, which would keep; the emulsion had been in a wet state for ten days, and was still all right.

THE CHAIRMAN remarked that Mr. Edwards had stated that it was not necessary to dye the plates at all. Tailfer's commercial plates were not dyed, and in appearance resembled ordinary gelatin-bromide plates.

MR. WELLINGTON stated that thioresine gave no visible stain.

THE CHAIRMAN thought that of the two comparative plates exhibited at the previous meeting the Monckhoven ordinary plate had not been used to the

greatest advantage; he should like to expose one on the same coloured diagram.

Mr. WELLINGTON had tried the diagram with ordinary plates, and the results were practically the same as those exhibited by Mr. Edwards; when he next tried orthochromatic plates they also agreed with Mr. Edwards's results.

The question was asked, "What is the best material for lining black twill envelopes to be used in place of dark slides?"

Mr. HENDERSON replied that an American cloth, black on one side and green on the other, as obtainable commercially in the market and used by ladies for needlework, was the best thing; he then showed how the American paper slides were folded; in reality, he said, they were made of thin cardboard.

The CHAIRMAN said that hitherto such slides had failed because sometimes, in pulling out the shutter, light was admitted.

Mr. HENDERSON responded that with due care such need not be the case. Plates would fog sometimes through certain kinds of wood.

Mr. F. M. EDWARDS said that he had called to see the platinotype prints yellowed under chemical tests by Mr. Pringle; he thought that it was merely a surface stain, and that any yellowness produced by chemical action upon a platinum print he could remove; at all events, if they would yellow the specimens of platinotype printing, which he then distributed, he would make the attempt and bring up the results at a subsequent meeting. Platinotype printing required good negatives; those by the wet collodion process were the best; the negatives turned out nowadays were not worth calling negatives at all. He then exhibited some beautiful specimens of platinotype printing, among which were some intentionally chemically coloured to give them the appearance of extreme old age.

Mr. HENDERSON said that Mr. Tunny, of Edinburgh, had years ago bottled up some platinotype prints in a strong solution of cyanide of potassium, and he (Mr. Henderson) believed that they were still as good as ever.

The CHAIRMAN did not think that the yellowing of the whites proved that prints were not permanent.

Mr. J. TRAILL TAYLOR remarked that he had some of the first—if they were not the very first—platinum prints ever made, and they were now as good as ever; they had experienced climatic vicissitudes in America and elsewhere, and had been under the influence of the air of London, which in itself was a great test.

Mr. W. COBB possessed the first platinum prints which took prizes, and they were still as good as ever.

Mr. TAYLOR had damped some of the first platinotypes, and suspended them over the gaslights in his former inner office, where the gas was nearly always burning, yet the prints did not suffer; some silver prints suspended under the same conditions suffered seriously.

Mr. EDWARDS had once put some over-printed platinum proofs in a sink, poured nitric acid over them, and put a lump of solid cyanide of potassium on the top of the whole; the paper was not benefited by the acid, but the images were uninjured.

Mr. W. H. HARRISON said that according to Willis's two earliest patents, salts of lead or silver were also used in sensitising platinotype papers; such salts would yellow or darken under the influence of sulphides. It had been announced, after Mr. Spiller obtained the yellowing results with platinotype paper, that the use of lead or silver in sensitising the paper would be abandoned.

Mr. EDWARDS thought that the prints tested by Mr. Pringle had not been properly fixed. When the baths of hydrochloric acid had fairly done their work it was impossible for the prints to yellow under tests.

Mr. COBB said that in the early days of platinotype he received samples of sensitised paper on which it was impossible to obtain pure whites. When once the paper had been subjected to a damp atmosphere, was it possible by any means to obtain good prints upon it?

Mr. EDWARDS replied that so far as his experience went it was impossible.

Mr. H. M. HASTINGS, when drying platinum prints between sheets of blotting-paper by the application of a hot iron, had found that they yellowed.

Mr. EDWARDS would develop some platinum prints at a forthcoming meeting of the Association. If such prints were not permanent it ought to be known, and the question settled one way or the other. None but iron and platinum salts were used in the manufacture of the paper.

Mr. HENDERSON asked how Mr. Edwards knew that, if he bought the paper ready sensitised?

Mr. EDWARDS replied that sometimes he sensitised it himself.

Mr. A. HADDON asked whether on such occasions he first bought his sensitising solutions of the Platinotype Company?

Mr. EDWARDS replied that he purchased them as stated.

Mr. HENDERSON did not see, under the conditions, how Mr. Edwards could know the constituents of the solutions.

Mr. COBB believed Mr. Edwards to be the highest authority living on commercial platinotype printing.

Mr. TAYLOR reminded them that Mr. Edwards had recently received a medal for some of his results.

Mr. J. HUBERT stated that he had received from Dr. Liesegang some of his transfer paper, by means of which the collodio-chloride print could be freed from its support, and used for lantern or other purposes. The film is primarily upon gummed paper commercially obtainable. The gummed surface is coated slowly with the collodion emulsion to get a thick film. The picture is printed until the shadows are dark black, and the lights blue. For lantern pictures the glass is coated with a ten per cent. solution of gelatine. The picture is squeezed down upon it under water, and after a time the paper backing comes off, after which the print is fixed with thiosulphate of soda, washed, and dried. The image can also be transferred to gelatine-coated paper if desired. Mr. Hubert then, by request, read in English an article by Dr. Liesegang from a German publication. This will be found on page 39.

Mr. HENDERSON said that twenty-five years ago there was a very useful albumenised transfer paper in the market, made by Ordish, of Paternoster-row.

Mr. COBB remarked that it bore the name of "diaphanous paper."

The CHAIRMAN stated that it was admitted on all sides that collodio-chloride prints were more permanent than ordinary prints upon albumenised paper.

Mr. HENDERSON added that in time the beautiful purple tone would go from

both classes of prints; he had found this even in the case of some which he had fixed down to glass with Canada balsam to protect them from the action of the air.

Mr. HADDON said that sometimes Canada balsam exercised a chemical action upon substances with which it was in contact.

Mr. TAYLOR stated that Canada balsam would act energetically upon certain salts.

The CHAIRMAN remarked that Mr. Bruce, of Dunse, Scotland, had been turning out collodio-chloride prints commercially for a long series of years, and they were far finer than albumen prints; his great difficulty was that the paper had such a strong tendency to curl in the solutions.

Mr. HUBERT had not found Liesegang's paper to curl. It was not collodionised on both sides.

Mr. HARRISON had recently read in *Le Moniteur de la Photographie* of Paris, that the curling difficulty was ameliorated in such processes by using a collodion containing a minimum of pyroxyline and a maximum of sensitising salt.

Mr. HENDERSON said that something was rubbed into the Wothlytype paper which made it nearly alcohol-proof and waterproof.

Mr. TAYLOR stated that this was done with arrowroot, to prevent the collodion from sinking into the paper.

Mr. Z. H. KINGDON had found black spots to come upon ready-sensitised paper when kept between sheets of blotting-paper charged with carbonate of soda.

Mr. HENDERSON said that that plan of keeping was good for ordinary paper and bad for ready-sensitised paper.

The CHAIRMAN remarked that Mr. Kingdon had better cut his ready-sensitised paper down to the sizes required for use, then keep it in a wide-mouthed bottle.

Messrs. W. J. Wilson and L. Medland were elected members of the Association, after which the meeting broke up.

CAMERA CLUB.

ON Thursday, the 13th instant, discussion at this Club on the subject of *Negative Films* was reopened by an address from Surgeon-General J. L. Ranking. Previous to the reading of the paper [this will appear in a future number] the Chairman for the evening, Mr. W. H. Hyslop, called for the exhibition of any objects of interest brought by members, and Mr. W. H. Crawford showed a compact actinometer, consisting of several negatives of varying densities, useful in carbon and other printing.

Mr. A. R. Dresser handed round some specimens of negatives on plates having the back surface of the glass finely ground, which added very little to the cost of the plate, softened the print, somewhat mitigated the evils of halation, and afforded easy means of retouching.

After the lecture Mr. W. Tomlinson exhibited an interesting series of paper negatives taken by himself in America in 1886, also bromide paper prints from the negatives.

Mr. W. A. GREENE referred to grain in paper negatives and lantern slides from them, as proving much more troublesome in most cases than Surgeon-General Ranking had found it. It was understood that grain appeared unless the film was just correctly exposed. In regard to the Woodbury tissue, it seemed that the new and improved make would not give the defects referred to by the lecturer.

After some remarks from Mr. DRESSER, Mr. H. H. O'FARRELL asked whether any one could say what the effect of the gums in the Woodbury tissue upon the film would be. Would the oxidation of the gums cause the breaking out of red or opaque spots?

Mr. SPIERS showed a convenient book of oiled sheets arranged alphabetically for storing paper negatives. He had found red stains come upon oiled paper negatives after ironing.

Mr. HARRIS said that the red spot on certain tissues was a silver spot, and could be discharged by cyanide; it was not oxidation, or ammonia would discharge it.

Mr. H. J. GIFFORD referred to the older processes in paper negatives, and gave his experience in the use of stripping films.

Mr. WALKER gave an interesting account of the preparation of paper and stripping films, and stated that paper contained in itself the elements of failure, as no calendering or pressure would entirely remove the marks of the matrix made upon the substance of the paper when it was in the pulp stage. This led to the introduction of stripping films, and even in these the paper support, which was of the purest kind and specially made, had to be coated with a soluble substratum, which was calendered down and the matrix pressed down before being rendered insoluble with chrome alum and made ready for further treatment. Without calendering the stripped film would be as grainy as the worst paper negatives. In regard to the development of the stripping films, there was no difficulty. Mr. Walker then gave a demonstration of the method of treating the films, which was followed with the closest attention. He explained fully the newly introduced use of collodion instead of the india-rubber solution, a change which made the processes more expeditious, cleanly, and certain. The gelatine backing was made with one surface smooth and the other of a ground character. Some perfect negatives on strippers made by Mr. Pringle were handed round.

After Mr. HYSLOP had related his experiences with negative films, the meeting was brought to a conclusion with votes of thanks to the Chairman and to the visitors who had contributed to the interest of the evening.

On Thursday, January 27, a paper will be read by Mr. E. R. Shipton on *The Wheel and the Camera*. Meeting from seven p.m., paper read at eight.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

THE first ordinary meeting of the above was held on Thursday, January 13, at the Free Public Library.—Mr. J. Alexander Forrest (President) in the chair, with a large attendance of members.

Mr. Edward H. Higgins was elected a member of the Association.

Mr. FORRESTER proposed, and Mr. B. J. SAYCE seconded, an extra hearty vote of thanks to Mr. P. H. Phillips for the more than ordinary amount of trouble he had taken to pilot the Association during the past year, which was carried by acclamation, after which the new Secretary (Mr. G. A. Carruthers) was formally introduced to the meeting.

Mr. FORRESTER then read the following address for the new year, and was listened to with much interest:—

In opening the business of the new year I wish to express congratulations, along with Livingstone's motto, "Fear God and work hard," with excellence as your aim.

The last year has been marked with considerable progress. Our annual *soirée* and exhibition of pictures has proved a great success. I am bound to state I am proud of the Association over which I have the honour to preside for its thorough practical aim, its cordiality, and its harmony.

We have long felt that a closer affiliation ought to exist between the various societies throughout the kingdom than at present exists (by the medium of the journals). We have opened up a correspondence with the Edinburgh and Dundee Societies, and nothing will be wanting on our part to make it productive of good. We also look forward to great results arising from the Congress that takes place at Glasgow in the course of this year.

We have for a long time felt that our monthly meetings got congested with variety of business, and in the hurry to dispose of it sufficient justice was not done to the various interests that presented themselves: as a safety valve to this state of things, a trial has been made of a weekly meeting in Liverpool, at the Grand Café Central, at four o'clock each Wednesday, where a cup of tea or coffee is provided, and the time does not exceed half an hour, so as to avoid any encroachment upon business demands, and conducted without any formality, so that all may express themselves freely, give their experience, and put forward questions for advice. I think this will be a success. At present the Association is not committed to this step, but it will give me much pleasure to bring it up at the next meeting of our Council. I would like also to open up this department and its privileges to kindred societies, such as the Astronomical, the Geological, and the Microscopical. I would embrace all the members outside Liverpool of every Society under the sun that presented their membership cards.

Our Association has issued its complete list of awards for 1887; this is entirely artistic; but why should we not give encouragement to the other two branches of our art-science, namely, chemistry and mechanical inventions? We have members highly qualified, why should we not encourage them? For six years I gave lantern exhibitions to the working classes of Liverpool, and I was deeply impressed with the high educational value of such work. This might be widely extended in the dissemination of technical knowledge as well as the boundless domain of art manufactures.

The grand sin of the photographic world is the squandering of plates on subjects perfectly worthless as pictures. My advice to all beginners is to reconnoitre for views, take notes of the best subjects in an artistic point of view, and the best time of the day when best illuminated; return home and watch for a good and suitable day, and then, and only then, proceed to carry out your determination. Depend upon it, hurry is the bane of photography as well as a good many things we meet with in our life work.

The experience of last year has proved that glass sensitive plates have held their own in producing works of the highest excellency. A new effort is being made to produce "isochromatic plates," that render "the relative value of colours with true gradation in the photograph."

The Eastman film has battled with criticism nobly, and the result is that the oiling difficulty is to be replaced by the transference of the film after fixing.

Printing from the negative is also getting light thrown into it.

Autotype, to my mind, stands supreme in permanence and detail. The growing demand for carbon enlargements will go on increasing until some easier mode appears possessing all its virtues, as another revolution amongst the many that have hitherto marked the progress of photography.

Mr. P. LANGE proposed, and Mr. LUTTON seconded, a resolution that in future all prints sent in for competition shall become the property of the Association, which was agreed to, as it was felt they would be a desirable addition when decorating at future *conversations*, and largely tend to minimise the expense attendant consequent on having pictures sent from a distance.

Dr. G. A. Kenyon, Medical Officer of Health for Chester, showed a specimen negative taken on a stripped film and mounted on glass, which, although taken under very adverse circumstances, was much admired when shown through the lantern.

Mr. Lange exhibited a number of large, highly-glazed portraits coloured by the new mechanical process about to be brought out by Cellerier's Syndicate, Limited, which were much admired and pronounced a great improvement on the old hand-colouring methods. It is of course impossible to paint any photograph so that it will have all the delicacy of colour and *chiaro-oscuro* of the image as seen on the focussing glass, the photographic basis will always remain and be visible under the colouring matter (except, of course, in the case of body colours), but the new process goes far to remove this deficiency, notably in the flesh tints. One portrait, that of an officer in full war paint, showed the improvement of the new process, the vermilion of the tunic having all the depth and semi-transparency of a vegetable paint. The metal portions of the uniform—sword, medals, &c.—were also beautifully rendered, not stuck on like patches of gold and silver leaf, as hitherto the case, but graduated in true high lights and shadow as seen in nature. The operation is said to be simple and the price very little in excess of the ordinary silver print.

The *pièce de résistance* of the evening was an exhibition by Mr. Frederick Evans with his new double oxyhydrogen lantern of nearly a hundred slides made by him from negatives taken during a six months' holiday in New Zealand, &c., last summer, and comprising shipping, landscapes, natives, animals, &c. Some exquisite views of the White and Pink Terraces were greatly admired, as were several of the geysers and boiling mud wells, and as a large tract of this part of the country has since been devastated by earthquake, the views had a more than ordinary interest. Mr. Evans very wisely departed from the usual cut-and-dry guide-book form of lecture, but explained each picture in a very terse and frequently amusing manner. The room not allowing of the usual sheet being put up, Mr. Phillips had arranged a very excellent substitute—a piece of drawing paper about six by eight feet square, such as is used by architects, and can be bought up to any length, he had mounted on two light wood rollers; this arrangement can be hung almost anywhere, and, with a small weight of any sort tied to the bottom, it hangs as flat as can be desired, gives a splendid picture, and has the great advantage of its portability. *Verh. sup.*, let other lanternists take a note.

A vote of thanks by the President to Mr. Evans for the treat he had afforded the members brought an agreeable evening to a close.

CHILTENHAM PHOTOGRAPHIC SOCIETY.

THE January meeting was held on the 13th instant. This was a lantern evening, Mr. E. Wethered, F.G.S., presiding at the lantern.

Slides were exhibited by the following members:—General F. Dawson, on his own bromide plates; Mr. W. C. Beetham, on Pumphrey's lantern plates; Mr. Joyner, on Cowan's chloride plates; Mr. J. Bull, on chloride plates; Mr. B. Jones, various; Mr. Wethered, photo-micrographs, &c., on chloride plates. There were also shown a number of slides sent by Mr. Pumphrey as specimens of his new lantern plates.

The amateurs had succeeded best with the chloride plates, many of their bromide slides failing in vigour and contrast. This difficulty had been overcome by Mr. Pumphrey in using his own plates.

Votes of thanks to Mr. Wethered and Mr. Pumphrey terminated the meeting.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE first meeting of this session was held at the Technical Schools, Bridge-street, on the 13th instant,—Mr. E. Howard Jaques in the chair.

Mr. B. Karlse exhibited photographs by Mr. G. M. Elton, of New York, which were admired for excellence of composition and finish.

Mr. W. D. Welford passed round some snow scenes taken by himself during the present month.

The recently-formed Lantern Section occupied the remainder of the evening in demonstrations of transparency making for the lantern.

Mr. E. C. MIDDLETON took up the wet collodion method, with the various operations, from cleaning the plate to the exhibition in the lantern, showing the transparency before toning and the result afterwards. Magnesium light was used for the exposure.

Mr. WELFORD then followed with the production from dry plates, and, exposing several of Pumphrey's new plates to gaslight, showed the simplicity of the work and the almost impossibility of failure. During the day he had exposed thirty plates, the exposure ranging, according to quality of negative, from thirty seconds to two minutes in the camera. He prefers copying in the camera to contact copying, finds slow development best, and uses Beach's potash developer, same as for negatives, gives good exposure, and uses a small quantity of citric acid in the hypo fixing solution.

Mr. R. P. TAYLOR gave his demonstration with Cowan's chloro-bromide plates, using the ferrous-oxalate and the ferrous-citro-oxalate developers. The copying was done by contact, and resulted very successfully.

Mr. A. PUMPHREY contributed a paper on *Printing Lantern Pictures by Artificial Light from Various Sizes of Negatives*. [This is expected for an early issue.]

SHEFFIELD PHOTOGRAPHIC SOCIETY.

AT the monthly meeting of this Society, held on the 11th instant,—Mr. W. B. Hatfield in the chair,

A discussion took place about the holding of a social evening at an early date, which was eventually determined upon.

Mr. A. S. PLATTS having read a paper on the working of the new Woodbury tissue, proceeded to develop a film which had been exposed at half-past three p.m. in November for five seconds, using $\frac{1}{10}$ f. The developer was Beach's potash. An Ilford rapid plate was developed simultaneously with the tissue, which latter was found to be at least equal in rapidity with the plate; the subject of each negative was the same.

Dr. MORTON, in proposing a vote of thanks to Mr. Platts, remarked that he believed that there was a great future in store for film photography, which, however, as a modern revival, was but in its infancy.

There will be a lantern slide competition at the February meeting; members to send in six slides made from 1886-7 negatives, to be passed through the Society's lantern with paraffine lamp, and shown upon a six-foot disc; the judging to be by the members present not being competitors.

YORKSHIRE COLLEGE PHOTOGRAPHIC CLUB.

THE second annual exhibition of lantern slides by this Society was held on Friday, the 14th instant, in the Chemical Lecture Theatre at the College.

There was a very large attendance of members and their friends, and the lantern was manipulated by the President (Mr. C. H. Bothamley) and the Secretary (Mr. Harry B. Hall). About one hundred and forty slides were shown, the contributors being Mrs. J. Knight, Miss S. Knight, Rev. R. W. Atkinson, Dr. E. H. Jacob, Messrs. C. H. Bothamley, A. Cooper, H. B. Hall, H. Ingle, P. Lund, A. E. Nichols, and W. Thomas. The subjects included landscapes from various parts of the British Isles and Europe, together with a number of figure and animal studies. All the slides were prepared on gelatine plates (chloride or bromide) from gelatine negatives. The finest exhibit was a series of views in Norway, by the Rev. R. W. Atkinson, which had been reduced in the camera on gelatino-chloride plates from $7\frac{1}{2} \times 5$ negatives.

CARDIFF AMATEUR PHOTOGRAPHIC SOCIETY.

THE monthly meeting of the above Society was held on Friday, the 14th instant,—the President, S. W. Allen, Esq., in the chair.

The following gentlemen were elected ordinary members: W. J. Austin and George Shepton.

THE PRESIDENT regretted that through a pressing engagement Mr. Kellar's lecture must be deferred until a future meeting. In connection with the Jubilee year he had pleasure in proposing that an exhibition be held some time in the autumn, and he trusted that the members would make a point of securing some good pictures, so that a perfect record of the town and neighbourhood at this interesting epoch might be handed down to posterity. He gladly noticed that the public meeting called by the Mayor had decided to encourage science and art in celebrating the Jubilee locally. Art had hitherto not received that recognition in Cardiff that it was entitled to, neither had the amateur photographer. In his opinion the photographic art was most deserving of encouragement, for, as a matter of fact, it was the only portion of scientific art that faithfully recorded the manners and customs of the world.

PHOTOGRAPHIC SOCIETY OF IRELAND.

THE usual monthly meeting of the above Society was held on Friday evening, the 14th instant, in the Royal College of Science, Dublin.—Mr. Howard Grubb, F.R.S., Vice-President, in the chair.

Mr. C. H. MELDON exhibited an enlarging apparatus which consisted of a lantern adapted for using the limelight, and fitted with a pair of eight-inch condensers, in front of which was the carrier for holding the negative (a half plate). On the same baseboard as the lantern was a sliding piece with an upright in which the lens was screwed. The apparatus was so constructed that it was capable of reducing as well as enlarging, so that a lantern transparency or an enlargement could be made from the same negative. Mr. Melton mentioned that, as a matter of practice, he had to keep the limelight as low as possible, as otherwise there was great difficulty in regulating the exposure, as it became a matter of very few seconds. He also mentioned a circumstance for which he sought an explanation, namely, that, in using a stop of a smaller size than about $\frac{1}{2}$ he could not get the picture sharp by any focussing. Mr. Melton's apparatus was not covered between the negative and the lens, and he said that he did not find it necessary to do so.

Mr. J. L. ROBINSON said that in his experience an oil lamp was superior to the limelight for enlarging.

The CHAIRMAN said that in his opinion the difficulty of the stop was entirely caused by the condenser.

Mr. Melton then handed round some enlargements done with the apparatus.

Mr. J. V. ROBINSON, on the part of Mr. Richard Robinson, exhibited Taylor's patent metal dark slide and also a collection of fine prints on Eastman paper.

The members then adjourned to another room where the Society's lantern was lighted, and a number of transparencies sent by Mr. Pumphrey, of Birmingham, as specimens of a new gelatine plate which he has brought out, were exhibited.

The following gentlemen were elected members of the Society:—Messrs. Julian George Butler, Louis Melton, Thomas Mayne, jun., and William Laurence.

Correspondence.

✂ Correspondents should never write on both sides of the paper.

THE PHOTOGRAPHIC SOCIETY.

To the EDITORS.

GENTLEMEN,—The annual meeting of the Photographic Society of Great Britain being now not far distant, it seems to be a not inappropriate time for the members of the Society, and for the photographic world in general, to devote a little thought to the working of the Society which ought to be to some extent a guide and example to other societies, now so numerous over the civilised world. And to a considerable extent the Photographic Society of Great Britain is a guide and an example to other societies; it teaches them all a grand lesson—which they will do well to study—of *what to avoid*. It is a shining illustration of the dangers of oligarchy. Not only is the blood of the Society frozen, but grievous wounds have broken out on its every part. Though it claims the position of being the leading Society, its meetings are stagnation compared with those of many other societies. Much of the time is consumed in enlarged editions of what may be found inside boxes of sensitive plates and rolls of cunningly prepared paper. With a few exceptions all new processes and ideas of late have gravitated towards the "Parent" Society rather than emanated from it. Complaints, loud and well-founded, have poured in from authoritative sources for years, and not a step has been taken to prevent a recurrence of the grievances. We hear that So-and-so is "inquiring into" such and such. Chaos has reigned in the hanging department, avalanches have swept the packing, Stygian darkness has enveloped the juries, and these matters are to be "inquired into," not, I hope, by the present wire-pullers, but by the Society, and by the photographic world at large, which has a right to expect something like rational management from the Society which claims to represent photography in this country.

This Society, alone in the world, expects its jurors to discriminate between the merits of portraits, landscapes, groups, "subjects," "pistol-graphs," dados, sea pieces, animals, and any other things in heaven or earth that can be photographed. This Society tells off certain irresponsible men to deal judgment among the pictures sent in the hope of finding room on the walls or on a dark corner of a screen. The members of this Society have the privilege of paying one guinea per annum, in return for which they get periodically a report which they can see equally well in the columns of the weekly press, and in return for which they lose rather than enhance any privilege they might be expected to have in the hanging of their pictures. Non-members pay for wall space, but members having already paid their guineas need not in any way be considered, they bring no further grist to the mill. Non-members from foreign countries pay no fees, I understand, and a fine swarm of "pistol-graphs" we sometimes see from them, a variation in practice somewhat hard to understand. And who can say whether our best pictures are hung or declined? I understand—I was plainly told—that this year the jurors saw all the rejected pictures; but where were the pictures when the jurors saw them? on the floor, or in the hands of some one, or where? And were the walls not already covered? and would it have

been an easy or a possible task to take down some frames and hang others when the jury saw the rejected frames? Over twenty frames of the Autotype Company were hung, while of four frames sent by the Eastman Company two were rejected and two hung. By what name can we call this? I sent three or four enlargements on bromide paper; the very worst was hung—it had been sent by mistake—while the others were rejected. I can quote other cases where good pictures were rejected and inferior ones by the same man hung. The hanging, in fact, seems to have been a perfect burlesque, and in certain cases very unfair. I say it was unfair to hang over twenty large autotype frames while other good work was unhung. Mr. Bankart points out that nine firms had no less than one hundred and fourteen frames on the walls, an average of twelve frames to each firm (nearly thirteen). Surely this is an outrage.

As matters stand at present I do not see how members, especially country members, can be expected to send frames for exhibition. Our frames are at the mercy of some irresponsible trio or quartette of men; they may be qualified for the post or they may not. And surely members have a right to a certain amount of space, subject of course to the possibility of the jurors ordering the frames away in case the frames were very bad or obnoxious in some way. Surely there ought to be a limit to the space allotted to single individuals or firms until at least the claims of members have been satisfied. And surely non-members' frames should be only second to members' frames, the non-members' hung after the members' work is all well placed on the walls. I am aware that the Gallery is not large enough to hold all the works sent, and I would be the last to clamour for the hanging of bad works, whether by members or not, but I have no hesitation in claiming for members the first right to be hung in good positions. A frame hung half a foot from the floor is a frame insulted, and a small picture ten feet high is a picture disgraced. They would be far better in the cellar. Members' frames to a certain limit should first be hung as well as possible. After that is done, non-members' work, and members' work beyond the limit, may be hung as the responsible hanger may best arrange. If members are not to have this advantage, who so foolish as to be a member?

The awards are to such an extent a matter of taste and opinion that I do not propose to say anything about them. The point that has always puzzled me is that so very large a proportion of foreign exhibits get medals. For my own part I never can see a proportionate superiority. It seems queer.

The maltreatment of frames in repacking has this year amounted to a scandal, and I for one am not contented with an assurance that the matter will be investigated, the carelessness ought to have been prevented; it cannot be cured by investigation. But it may be prevented for the future by the appointment of one responsible person paid for the work and skilled in the work, and until such an arrangement is made, both for the hanging and the packing of frames, no justice will ever be done, no satisfaction ever given. Where several people have the charge of anything, nobody takes any charge of it. The proverb about "cooks" is not of yesterday.—I am, yours, &c.,

ANDREW PRINGLE.

PERMANENCE OF PRINTS.

To the EDITORS.

GENTLEMEN,—To a working trader like myself, anxious for the reputation of bromide and platinum prints alike, Mr. Pringle's account of his experiments is of momentous interest, and no one knowing his position in relation to the matter as an enthusiastic and painstaking amateur will undervalue the results he has recorded or doubt his disinterestedness in publishing them.

"All the contributors, save only he,
Did that they did in quest of further trade, Sir;
He, only, in a general honest thought
And common good to all, made one of them.
His aim was simple; and the elements
Were such stuff to him, that Nature might stand up
And say to all the world—'This is my Man!'"

Disastrous as some of your correspondents seem to regard the results of Mr. Pringle's experiments, I will not allow myself to be seriously depressed by them, because, whether correctly or not, I think I detect a reason for the discolouration which has escaped Mr. Pringle's usually acute observation.

Analytical chemists are well acquainted with the difficulty of absolutely removing the *final traces* of iron from any salt which for their purposes must be entirely free from that contamination. Carbonate of potash is a familiar instance, which by the difficulties attendant on the processes of its purification is raised from the price of fourpence per pound in the crude state to half-a-crown an ounce in the absolutely pure state.

It is almost unnecessary to remind your readers that iron forms the reducing or developing agent in the bromide and platinotype processes, and I would suggest the question whether the discolouration of the whites in Mr. Pringle's experiments may not have arisen from the formation of *minute traces* of sulphide of iron, stimulated, in the case of the platinum pictures, by the well-known power of that metal to absorb hydrogen (from the H_2S) with an avidity comparable only to that of a sponge for water?

I would recall, also, the fact that neither bromide enlargements nor

* *Julius Cæsar*, Act v., Scene 4 adapted.

platinotype prints are likely, in the ordinary course of events, to be immersed in a solution of H_2S , and if steel engravings were similarly treated I think it not improbable that the all-pervading iron in the woody fibre constituting the paper would, after thirty-six hours' immersion, show similar discolouration, which would go far to support the opinion that bromide enlargements, platinotype prints, and steel engravings, are "pretty much upon a par," at least in relation to sulphuration, and I think it will be conceded that any bromide or platinotype which, *ceteris paribus*, behaves like a steel engraving, is for all practical purposes permanent.—I am, yours, &c., J. MARTIN.

4, Park-villas, New Southgate, N.*

To the Editors.

GENTLEMEN,—In your issue of January 14, Mr. Berkeley is again in print with many statements which seem to me quite irrelevant to the discussion upon the permanency of prints upon bromide paper. My reference to the yellowness of some platinum prints was based upon specimens made by platinum workers of acknowledged skill, and was in no way intended to disparage the process. Mr. Berkeley's admission that the platinotype, as well as the carbon process, fails utterly unless the sensitising materials are carefully removed, is cause for hope that the opponents of the bromide process will in time discuss this question with at least an approach to fairness. Meantime may we hope that he will give the waiting world a detailed statement of his tests, by which he has proved so conclusively to himself the utter worthlessness of bromide paper?—I am, yours, &c.,

WILLIAM H. WALKER.

*Office of the Eastman Dry Plate and Film Company,
13, Soho-square, London, W.*

ON PROCESSES AND PERMANENCY—A REPLY.*

To the Editors.

Now, to turn to Mr. Dunmore's letter, he does not seem to see that the point is that, notwithstanding the greater knowledge and care displayed during "comparatively recent years," the albumenised prints—often turned out, it is said, with care—*still fade*, while others, though carelessly done, remain intact; whence the enigma, how to produce unfading silver prints, and, secondly, how to preserve them! It is even said that silver prints are at the present day greater culprits than ever they were. As I said in my last letter, in these considerations lie the *crux*.

What I mean to enforce is this, that if we take one of Mr. Dunmore's "thirty years'" prints and keep it under other conditions—not as "floorcloth"—it may very likely fade. Secondly, that if it does not fade, can Mr. Dunmore (or any one else) turn out any number of the kind of which he can say, placing his hand upon his heart, that they will behave similarly if similarly treated (though the conditions of keeping need not necessarily be similar, if really reasonable)?

It is new to me to see the constitution of an albumenised silver print put forward as a probable reason for lasting qualities. "What is one man's food is another's poison;" so we have the bromide paper makers claiming that *their* image is metallic silver, and that no silver nitrate comes into contact with the paper! So, you see again, it is "*quot homines*," &c.!

I do not take "marking ink" on linen to be very lasting. Some inks wash out, others yellow, and I do not know that any will outlast, say, a pocket-handkerchief. However, we are not discussing marking inks nor handkerchiefs (though I quite note there is more of "analogy" in the one than in the other). No doubt the inks are several of them "permanent" enough for practical purposes (handkerchiefs being generally renewed from time to time) to enable the vendors to sell them as such. For what evidence have we that an albumenised print is like a pocket-handkerchief *plus* "marking ink"? Again, I say, we do not want so much *surmise* but more *proof*, or at least *evidence*, which I have alluded to as "analogy."

Mr. Dunmore seems to ignore the fact that though presumably "we have some permanent element in a silver print" (an albumenised one), yet prints containing this same element (gold) fade, just as though the "permanent element" were not there. However, this is rather "a bone" for the advocates of albumenised printing and bromide printing, respectively, to pick than for me.

Mr. Dunmore does not even now see that I do not say that a print which will not stand the tests necessarily is not permanent, but that such tests properly carried out by independent individuals and successfully passed would, as in the case of platinotype, convince all but the most sceptical of their permanency. Instead of such tests being carried out—at least, passed—we are asked (I refer not only to Mr. Dunmore) to take as an article of faith the permanency of what I termed "these untried strangers" (or are they "old friends in new clothing"?).

It seems some of us prefer now to make statements on the strength of "faith" rather than on the "fact" as far as it is known. This system certainly has much to recommend it when facts do not fit in well! But I do not see why "faith" should serve for silver, while facts were demanded of platinotype. "Sauce for the goose is sauce for the gander" when *early* recognition of permanency is sought for.

* Concluded from page 31.

In writing as I do upon this subject I claim that there is no "*ipse dixit*" on my part as regards platinotype. Prints which will stand eight years' keeping, combined with treatment by every chemical except *aqua regia*, must lick Mr. Dunmore's "marking ink" into fits for "permanency!"

I say that we have guarantee for "platinotype and carbon 'lasting' unchanged," for this reason, that both platinum and carbon in fine division are known to chemists not to alter their constitution by being kept in any reasonable—or, I might add, unreasonable—way whatever. In specifying "carbon," I mean *carbon*, and not any other pigment, though we have the Autotype Company's assurance that in their methods only stable colours are now used, and I do not question their authority for saying so. Besides, "carbon printing" is not necessarily autotype. Further, it is absolutely certain that platinum will outlast any paper ever manufactured or likely to be so. Any fool can understand this, and I add that the platinum image will last longer than the paper support. This is strikingly illustrated on boiling a print with nitric acid; the paper is dissolved and the platinum forming the image falls down to the bottom of the vessel. Analyse it if you like.

Of course this is merely a coincidence, but a valuable one from my point of view. I quite admit—as I have admitted—that a print *may* be entitled to be termed "permanent" which has its image completely decomposed by even weak nitric acid, and by other tests. Put any kind of silver print into nitric acid of any strength (which need not destroy the surface of the paper), and into several other well-known chemicals, and note the effect. Do the same with platinotype, and you will have a very pretty and suggestive experiment.

I particularly stated in my last letter that I agreed with Mr. Dunmore that the "violent treatment" was not very satisfactory, being too stringent as a test of permanency, but that, when passed, it is a very convincing one, and the only test possible when at the "outset" "faith" is not so strong as it appears to be in some of your correspondents.

Mr. Dunmore's "thirty years' prints," which have withstood "all that time" town air, must be the "exceptions which prove the rule!" I have some early *carte* portraits of members of my family, several of them are still good: but a brother of mine, who had similar prints given to him at the same time, has not one which has not faded years ago. Yet my prints have had more town air than his; but I think I have kept mine drier at all times than he has at times done. Mr. Dunmore is exacting in the length of time he requires to decide the question of permanency of albumenised prints. Well, there can be no harm in leaving the question open to doubt for another thirty years; this is very different to taking the "*benefit of the doubt*," and being backed up in the course by others. The bromide paper makers, who take this course, should deem themselves lucky—and probably do laugh in their sleeves—because what was "sauce for the goose" is not apparently to be sauce also "for the gander."—I am, yours, &c., HERBERT B. BERKELEY.

P.S.—It is becoming increasingly evident, as I presumed it might, that each writer on this subject is setting up a different standard of what each terms "permanency" that may be best adapted to the process each respectively advocates. It might have been supposed that what constitutes "permanency" in a paper photograph was well understood—felt, perhaps, better than defined—and that no practical difference on the subject could arise. One would also have thought that the nature of the evidence, in lieu of proof, required to support the claim of "permanency" would be patent to all.

As regards the unalterability of unvarnished gelatine negatives, it must be remembered that they are viewed by *transmitted* light. I think there must be several readers able to recall to mind a very uncanny appearance on such negatives viewed by *reflected* light after they have been kept some months or years in the air of London.

Let some of our "Clubbists" in search of a subject examine their racks and "shelved" plate boxes, and, when found, make a note of "this fact, that a positive image is as a section of the negative one, and that the former is backed up by white paper."

H. B. B.

San Remo, December 21, 1886.

THE AMATEUR QUESTION.

To the Editors.

GENTLEMEN,—Having been attacked on two sides, by friend and foe—by the latter for opposing them, and by the former for opposing the results of the latter—I desire, through the medium of your paper, as the only way of approaching them, to explain to the members of the Liverpool Amateur Society what may seem obscure, and especially as a few remarks in one of your late issues might lead some to suppose I have been in that Society under false pretences, as many even now believe.

Three years ago I resigned, or wished to resign, my position in the above Society, not deeming myself privileged, according to the rules, to remain therein, in consequence of the publication of a portion of my work.

It was with great difficulty I could prevail on the Hon. Secretary to bring my resignation before even the Council, he pooh-poohing it as absurd. The result, however, was that my resignation was refused, and I was informed that so long as I restricted myself to landscape work and did not open a studio for portraiture no objection would ever be taken to

my remaining an ordinary member. And no voice was ever raised against this decision. About the end of last year, however, when the present Hon. Secretary resigned, I had occasion, in the interests of the Society, to object to the nomination of one member to this post,* and within a few days, at a Council meeting at which I was not present, a resolution was carried after two and a half hours' discussion, and of which no previous notice had been given to me, which practically excluded me from the Society.

At the next meeting of the Council, which I purposely refrained from attending, this resolution was rescinded, and at the annual meeting following I was again unanimously re-elected Hon. Treasurer. Yet two charges are now brought against me—first, that I have persisted in remaining a member of the Society against its rules and against the wishes of the members thereof, and that by such action I have injured the Society and caused much ill-feeling. To both of these I can give but one answer—an utter denial, having, as I have already stated, purposely refrained from speaking at any meeting but the one aforesaid, in order to avoid the chance of disagreement.

That the Society has been injured and its interests neglected I affirm, and great blame is due to those who have caused such, and I feel sure that the members will acquit me of all blame in the matter.—I am, yours, &c.,
January 15, 1887. J. H. T. ELLERBECK.

MR. MANSFIELD ON MR. PRINGLE.

To the Editors.

GENTLEMEN,—I protest against Mr. Mansfield's assertion or assumption that the "primary object" of my article on Permanence "would appear to be to discredit platinotype, and thereby to annoy its great champion, Mr. H. Berkeley." Mr. Mansfield, not content with this deliverance, goes on to accuse me of being a party to personalities in the discussion. Where does Mr. Mansfield find any evidence for his accusations against me? If I doubt certain assertions, test them and disprove them, am I to be accused of bearing a grudge to the asserting parties? Why should I seek to annoy Mr. Berkeley, whom I look upon as one of our best authorities on photo-chemistry? I might well have been annoyed myself by Mr. Berkeley's last letter, but unfortunately for Mr. Mansfield my article was, as you know, in your hands and in type before Mr. Berkeley's letter appeared, and, as you also know, it has not been altered since. There must be an end to all discussion if we are to be accused of personal feeling whenever we disagree with others. And as to personalities, where does Mr. Mansfield find me indulging in them? He will find a fair sample in Mr. Berkeley's letter already referred to, but, so far from countenancing them, I declined firmly to "follow any man in such a line of argument." I have not one grain of ill-will against platinotype, much less against Mr. Berkeley. I call platinotype a "permanent" process, only I assert that platinotype prints are hurt by sulphuretted hydrogen and moisture, and I have sent proofs of my assertion to your office. I also assert that sulphuretted hydrogen and moisture hurt bromide prints, and I have sent proofs of that to your office. I also assert that albumen prints are more damaged by H₂S than are bromide and platinotype prints, and I have sent proofs of that also to your office. Where, then, appears any unfairness on my part, or any personal feeling? I have distorted nothing, suppressed nothing.

From Mr. Mansfield's remarks about albumenised paper I gather that he has neither read with sufficient care what I wrote nor tried my experiments himself.—I am, yours, &c.,

ANDREW PRINGLE.

Craigleugh, Langholm, January 15, 1887.

DON'T GIVE PRINTS.

To the Editors.

GENTLEMEN,—Mr. H. Y. E. Cotesworth, in a kindly criticism, which you publish this week, on a paper I read at the Camera Club, mistakes the meaning in my mind, whether my words conveyed it or not. I may say at once the intention of my paper was wholly suggestive of individual practice, without any idea of one of those suggestions becoming a rule that should in the slightest degree control an amateur. When I said, "Don't give prints away," I really meant to preach what I practise. If I ask any one to sit to me to whom I could not offer money I give one print off each negative I take; if more are wanted it is an understood thing that a little photographer in my town can have any negatives I take to print from, and would supply copies as I suggested. The poor model—and I not unfrequently take a beggar from the streets—I pay in coin, and the transaction ends. My object is to send grist to the little photographer's mill. It is also to avoid what has become, I think, a great evil—the spread of false notions as to the cost and value of photographic prints.

*The objection I made to the nomination of Mr. Beer to the office of Hon. Secretary was this, that since he and others had founded the Birkenhead Society all their energies were devoted to that Society, to the neglect of the Liverpool Society—for this I do not blame them, having no right to do so; but, knowing this (and this is proved by a comparison of the reports of the two Societies), I thought it more advisable that we should have as Secretary a gentleman who had always and would continue to devote his whole and undivided attention to ours—i.e., the Liverpool Society. Unfortunately, the cap made for Mr. Beer fitted many others, including, though I never intended it, several members of the Council, our own Secretary, and the President, who is also Hon. Secretary of the Birkenhead Society, and our late President, who also held a similar position, and I very soon found the whole of these gentlemen against me.

Mr. Adams photographs, and he gives prints here and prints there. To Mr. Beattie, who sat to him, he has given half a dozen; of course, they cost but little, say his friends, or he would not do so—less really than the drugs of the chemist, for which he charges so much in medicine. Mr. Beattie wants more, and says he knows he can have them if Jane asks for them. Of course he can! It is the James that complete the mischief. "Oh, dear Mr. Adams, Charles does so like the picture he sat for, but he has given all those away, and I am sure you would let him have a few more, for I want a couple; and, oh! those lovely views of Wales you showed me, would you, oh! would you mind—some time you know—giving me a copy of each of those?" This of course knocks poor Adams over, and when Miss Courtenay has asked him for a few of those prints in which Charles Beattie is so nicely taken—"so clever, you know"—he finds he has printing on hand for a fortnight. Of course, if Mr. Adams likes to sow his work broadcast amongst his friends he has, and ought to have, a perfect right to do so. Appreciation of what he does is the pleasurable payment of successful work. I am supposing cases where the requisition for prints is understood to be one of the smallest asked favours on the one part and irksome to comply with on the other.

I have found that non-photographers consider a print a print, and make little distinction between the value—that is, cost to the producer of a half-plate and one 20×16. I have found, too, a decided preference for platinotypes of large size. But, of myself, enough. In my paper I advised the non-bestowal of prints largely, entirely because I see it liable to convey to outsiders the impression that a negative once secured, prints from it can be taken in no time and at no cost. I fear the whole thing is made too cheap and that the interests of the profession are affected by it. At my home I lay hands on a little shop only too glad to earn a few extra shillings by printing, but I can easily see it might be very different in London, where distances are so great and where a risk might be run by over trust in lending negatives. It is really another instance of what is good for Tom being bad for Harry.

I must add, Gentlemen, the remark that, although I may think Mr. Cotesworth rather overrates the difficulties of good treatment of figure, I feel his commendation of my own work a great compliment.—I am, yours, &c.,
Melton Mowbray. WILLIAM ADCOCK.

GLASGOW.

To the Editors.

GENTLEMEN,—Some months ago you are aware there was a meeting of professional photographers held in Glasgow to consider matters connected with the trade, and how best they could keep themselves informed on all professional matters. It was considered this could be managed in connection with the existing Society, and meetings of those in the trade (earning their bread by it) were to be held an hour previous to the ordinary meeting. Notices have regularly been put on the circular, but there has been nothing done; so, for the present, Glasgow has somewhat dropped the question. It is well to state so in your JOURNAL, because you were kind enough, in a leader, to speak favourably of the matter, and gave some valuable suggestions which would be of great use if carried out through some society or by some newly-formed one.

You see, Gentlemen, we, as professional brethren, don't meet very often, and although there is a deal of good work done yet it stands so much between cheap workers that little sympathy exists. And when one and another leaves their clerkships, and after a little amateurism open glass-houses and push in all directions, and arrange for prices and customers in all manner of ways alongside or on every side of the older men, who cannot go into the new tricks of trade, you see it is not easy to meet in business converse, because we are agreeable men and don't want to differ. So we must just sink or swim the best way possible. The principle will likely hold good—the survival of the fittest, or "the good are taken away from the evil to come."—I am, yours, &c.,
Glasgow, January 15, 1887. ARCHIBALD ROBERTSON.

THEALE PHOTOGRAPHIC EXHIBITION.

To the Editors.

GENTLEMEN,—Kindly note that the Theale Photographic Exhibition can be easily reached by through trains from Paddington, starting at 1 p.m., 3.30 p.m., 5.10 p.m., and 6.30. The best train is the one at 5.10; it reaches Theale at 6.20 (no change of carriage), and a train returns at 8.37. I think, when you see the list of exhibits, you will say that the collection has the pick from the Pall Mall show, and none of the rubbish, with other good work added.—I am, yours, &c.,

ALFRED A. HARRISON, Hon. Secretary.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

To the Editors.

GENTLEMEN,—Kindly allow me to remind your readers that application for space at our forthcoming exhibition of photographs should be made to the Secretary, Exhibition, Newcastle-on-Tyne, on or before January 31, and, to save time, 5s., the entrance fee, may be enclosed. We hope that exhibitors will be numerous and representative, thus

enabling us to have a display of an interesting and attractive character.—I am, yours, &c.,

J. PIKE, Hon. Secretary, Newcastle Photographic Association.
16, New Bridge-street, Newcastle, January 18, 1887.

A DISCLAIMER.

To the Editors.

GENTLEMEN,—What have I done that I should have been honoured (as I have been in your last number) by having my name appended to what is obviously an editorial article?

I certainly did send an article for insertion, its subject being the *Sulphuration of Platinum Prints*, and which I telegraphed to you at the last moment to hold over for a week, as I wished to supplement my remarks. Kindly put the matter straight, and inform your readers that the article to which I have referred as bearing my signature was not written by—Yours, &c.,

C. BECKETT LLOYD.

[Our explanation can be given in a few words. When Mr. Lloyd's telegram was received the JOURNAL was made up for press: his article was removed in accordance with his request, and an editorial sub-leader which was standing in type ordered to be inserted in place of it. In doing so the printers allowed the signature to remain *in statu quo*; hence the anomaly. Mr. Lloyd's article in its completed form appears this week.—EDS.]

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange cabinet accessory, nine changes, for posing chair.—Address, G. & I. Hall, 26, Westgate, Wakefield.

10x10 leather bellows camera, brass bound, swing back, single back, exchange for whole-plate tourist with one or more double backs.—Address, W. J. ROBERTS, Photographer, Mold.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessary for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

A. BELL.—All the more useful formulae will be found in the ALMANAC.

ENGINEER.—The lens being understood to be symmetrical, it matters not which end is placed next the negative.

A. J. W.—Send on a print or two, that we may see the effect of the treatment; but, in the meantime, it may be well for you to repeat the experiments before publishing the results.

S. W. C.—Dammar dissolved in benzol forms one of the best varnishes for negatives that can be applied to the plate without heating. It is not, however, so durable as alcoholic varnishes with a shellac basis.

S. J.—We do not attach much importance to the statement, though it may, nevertheless, be correct. Probably nothing further will be heard of the matter. A respectable solicitor will give you better advice than we can.

H. H. NEWMAN.—The picture appears to be fairly well illuminated, and we can see no reason for altering your present method of working. For half-plate negatives a condenser of about nine inches in diameter is necessary.

S. WALLER (Hants).—If you want your prints to be unaffected by light, avoid the use of pink-tinted paper like that enclosed. Such paper changes very rapidly when exposed to the light. It is impossible to say if the mounts contain anything deleterious without making a chemical examination.

J. N. (Herts).—One hundred grains of silver nitrate to the ounce of water is far stronger than is ever used for sensitising paper now-a-days. At one time this proportion was sometimes used, though not as a rule. Sixty grains is now looked upon as a strong bath, and this strength we advise you to adopt for your particular work.

CHLORIDE.—1. The tones appear to be very good, though they may not be those you desire. Almost any tint can be obtained, according to the time the prints are allowed to remain in the bath. Why not try the old fixing and toning bath by way of experiment? that may perhaps answer your purpose.—2. If you, by working in the studio, cannot decide which is the best end to place the sitter, we scarcely care to hazard an opinion.

MACBETH complains that many of his negatives taken last summer are showing a curious appearance on the varnish, something like "fish scales," and sends a sample. The cause is very clear: the hyposulphite of soda has not been thoroughly removed, and has therefore crystallised out on the surface. If the varnish be dissolved off the negatives can be rewashed to remove the salt. If this plan be adopted it will be well to treat the plates with alum as a safeguard against frilling, which sometimes takes place under this treatment.

W. B. CASSINGHAM writes: "Gelatine has been recommended for mounting prints; will you kindly inform me, in 'Answers to Correspondents,' how to prepare the gelatine as a mountant?"—For ordinary purposes the gelatine is simply dissolved in water and used warm; but if the prints have to be mounted with a margin and cockling avoided, part of the water should be replaced by alcohol. The amount of alcohol that may be used is dependent upon the gelatine. Some samples will bear a much larger proportion of alcohol without precipitation than others.

J. E. GUBBINS writes: "Can you or any of your readers tell me whether Durnford's 'Right-about-turn' shutter is a durable one and not likely to get out of order? Its lightness, small size, and neatness, recommend it, but I have heard that it has a trick of striking work."—In reply: There is no reason why, if well made, the shutter should stick; the principle is good. One or more that were shown in the last Exhibition certainly did stick, but this may have arisen from their having been handled carelessly by the visitors. We cannot, however, speak of them from personal experience.

GEO. SMITH says: "I have lately taken a few snow scenes, and the negatives, owing to the long time taken in development, are of a deep yellow colour. I cannot remove this stain by the ordinary 'clearer' (acid and alum), as it has had no effect even after a three hours' soaking. Can you recommend something which would act as a decoloriser? If so I should feel greatly obliged. The negatives were developed with soda and pyro, and if the stain was removed they would give good prints."—The yellow stain frequently caused by long development with the soda developer is often very difficult to remove—sometimes impossible. Perhaps some reader can assist our correspondent.

G. W. ATKINS writes: "I should be glad if you would inform me the reason why bichloride of mercury blackens a wet plate but bleaches a gelatine one, requiring ammonia or other application to give a black effect. The textbooks say that bichloride behaves the same in both cases, that is, it bleaches by forming a double salt of silver and mercury. This has not ever been the case with me in reintensifying a wet plate after the usual pyro-silver intensifier."—Bichloride of mercury acts in a similar manner on a wet plate as it does on a dry. We fear our correspondent is not a close observer, otherwise he would notice that when the bichloride is first applied it slightly darkens the image and then commences to bleach it in exactly the same way as it does a gelatino-bromide plate. When the image is bleached it can be blackened the same as in the case of a dry plate.

F. M. S. writes as follows: "Will you kindly tell me whether the registration of a photograph at Stationers' Hall gives the owner of the copyright power to prevent the registered photograph being sold without his permission? A dealer in photographs here is buying my photographs, some of which are copyright, from some firm whom I supply away at trade price, and is selling them at a trifle over the cost instead of at my usual price, because I refuse to supply him direct. This I cannot do as I agreed only to supply three people here. These three say if I do not stop the man from underselling them they will not buy any more. I cannot tell from which of the wholesale houses I supply that he is obtaining the goods, but if the fact of some of the pictures being copyright will enable me to stop him I shall do so."—Our correspondent certainly cannot stop the sale of the pictures. He having sold them the purchaser can of course dispose of them at any price he chooses. If any of the copyright pictures had been pirated the case would be different, and then the sale could be stopped.

* * Several correspondents in our next.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The usual monthly technical meeting of this Society will take place next Tuesday, January 25, at eight p.m., at 5A, Pall Mall East, when the subject of orthochromatic plates will be discussed and results shown.

LECTURE ON LENSES.—On Wednesday evening, the 26th instant, a lecture on *Photographic Lenses* will be delivered before the Society of Arts by Mr. J. Traill Taylor. Those, not members, desirous of being present will have facilities afforded for their admission by applying to Mr. Treman Wood, the Secretary. It is understood that the lecture will, by request, be repeated on an early occasion at the North London Photographic Society.

PHOTOGRAPHIC CLUB.—On Wednesday, January 26, 1887, will be held the exhibition meeting of the Club of work done by the members during the past summer. Photographs must be delivered at the hotel, addressed to the Hon. Secretary, some time before four o'clock of the day of exhibition. It is proposed to make the evening additionally attractive by the introduction of music, singing, recitations, &c. Gentlemen who will give their assistance are requested to communicate with the Hon. Secretary.

DINNER AND PRESENTATION TO MR. GLAISHER.—It is now an open secret that a fine marble bust of the esteemed President of the Photographic Society of Great Britain has been executed by a rising young sculptor by request of several of Mr. Glaisher's friends, and is pronounced by all who have seen it to be an excellent likeness. It is to be presented to Mr. Glaisher at a dinner at the Holborn Restaurant on Monday, the 31st instant, Captain Abney and Mr. W. S. Bird respectively Chairman and Vice-Chairman. Any personal friends of Mr. Glaisher can have tickets (price 5s.) on application to Mr. Bird, 74, New Oxford-street, W.C.

No. 1395. VOL. XXXIV.—JANUARY 28, 1887.

COAL-TAR COLOURS IN PHOTOGRAPHY.

THE use of the term aniline dyes, or aniline colours, is so frequent, and usually so incorrectly applied, both popularly by the masses and specifically by the photographer, that we purpose giving a brief account of the particular class of colours thus spoken of, as already they subserve so many uses in photographic operations, and one series bids fair to be of the highest importance in the photography of the future.

The whole development of the manufacture of these colours has taken place within the memory of some of the younger of our readers, for it is only just over thirty years since the world was astonished by the production of the first of the series, the once fashionable mauve, which really was an aniline dye, and the popularity of which, and its congener magenta—equally correctly so named—led to the vulgarisation of the technical term aniline, which came into common use, and has since been retained by the public for use with all succeeding colour inventions connected with coal-tar, though they may only be connected in the most remote degree with the chemical in question.

When coal-tar is distilled an immense variety of substances, liquid and solid, come over, and it is the business of the tar distiller to obtain them in the most economical manner, in a separate form, the various processes for carrying on the operations, or for purifying the distillates, being unnecessary to be detailed here. Practically the products of commercial importance in connection with our subject are the hydrocarbons and the phenols, the former consisting, as their name implies, of hydrogen and carbon, and the latter containing these elements and oxygen also. The well-known carboic acid is a typical, and the most important, phenol.

The hydrocarbons of importance are benzene, toluene, the xylenes, naphthalene, and anthracene; and by the aid of the two first named was that aniline obtained which in the production of mauveine and magenta gave rise to the well-worn aniline dye title. In attempting, in this briefest of sketches of the most intricate of all modern processes of technical and theoretical chemistry, to treat the subject in a manner at once popular and interesting, while sacrificing as little scientific accuracy as possible, it will be understood that we write not for experts but for our readers generally.

We may say, then, that these colours may be divided into groups according to the substances employed in their production. We first have those from benzene and toluene, as already spoken of, those from the phenols, from naphthalene, and, lastly, from anthracene.

The first division contains all the dyes first invented, and others; thus the magentas, many browns, oranges, greens, blues, violets, and blacks. The second, embracing the phenols,

contains the yellow dye, picric acid, and some other important yellows, besides a very permanent green, and other colours. The eosines may be included in either this division, the preceding, or the succeeding. Pyrogallie acid also belongs to it. The third division contains some reds and yellows, and the important bodies named azo dyes. The fourth division includes alizarines, purpurines, and alizarine compounds.

It is thus seen that photography borrows from all of these groups, there being magenta (including roseine and fuschine), aurine, eosine, and the alizarine colours (used in carbon printing) respectively, with many others, not to speak of the raw material, benzene itself. One of the most important uses to which these colours have been put, leaving aside for the moment the manufacture of ortho or isochromatic plates, is to form colour screens to modify the light in photographic operations, and there can be no doubt that owing to the immense range available, almost any requirement can be satisfied by their aid. It must, however, be admitted that for continuous use as a daylight colour screen they are not to be recommended, owing to their comparative fugacity when exposed to strong light. We do not mean, in so saying, that coal-tar colours are more fugitive than other dyes that might be obtained, for such is not the case. They are made as "fast" as any dyestuffs ever employed by man, but the number of colours fast as against light is not very great, and, further, no colour in the world that would be of photographic use will stand continuous sunlight for example. The result of the use of these colours to screen a window exposed to a strong light would be that in course of time change would occur, and so gradually, that it would not be noticed, fogged plates might then result before the cause was thought of, for the change would not necessarily be visible to the eye.

Again, granted the possession of a series of colours suitable apparently for photographic purposes, the eye again would be no guide as to their value. Of course, the test of experience could any time be applied; but there is a tendency to choose a colour that looks as if it would not let light through, and, scientific though our processes are become, there are not many photographers at present who employ a spectroscope. Such an instrument occasionally used would quickly render perceptible an alteration that permitted any harmful visible ray to pass, though by the eye the change might remain undetected. As to the actual facts of visible fading, we may say that the two colours most known to photographers—aurine and roseine—will lose their colour very rapidly in sunlight, and quickly in ordinary daylight.

It is quite a mistake to suppose that a yellow dye—take, for example, picric acid—appears yellow because it absorbs all

other rays but the yellow, and that they alone pass through. The real explanation is that it absorbs the colours complementary to yellow, but permits reds and greens of various shades to pass, which latter, having the effect of white upon the eye, simply affect the light by making the yellow appear paler by its admixture with white. A knowledge of these facts would be of material aid in selecting screens.

Magenta, again (using the well-known term, for roseine and fuschine are equally magentas—salts of rosaniline), when in very strong solution allows only red to pass through; but when diluted, it only absorbs the rays between D and E, thus leaving a photographically active margin to pass through. Captain Abney showed how, by using an aurine and a roseine screen combined, the actinic rays passing through the one were kept back by the other; and thus a perfect light screen might be made, which for occasional experimental work would be invaluable. We should not recommend it as a permanent dark-room window screen where a plentiful supply of daylight had to be kept out.

Again, the absorptive power of a given dye is altered according to the medium in which it is dissolved, and it is quite possible for the same rule to hold good with what might be termed the cementing material when it is laid on glass. Thus shellac varnish, collodion, or either with glycerine, have been recommended as media for conveying a coating of colour to glass; it must not, however, be accepted as a matter of course that the effects obtained with one are the same as those which may be produced with the other.

We have said enough in a general way, perhaps, and will now turn to the colour that attracts the greatest attention amongst photographers at present—eosine, although this name, while used to specify a particular dye, is really properly applied to a group of dyes. This colour, however, is of sufficient importance to merit being treated by itself, and we will, therefore, defer to a further number all discussion of the remarkable series of bodies that in connection with colour sensitive plates is exciting, and for some time to come will continue to excite, so great an amount of attention amongst all photographers, scientific and practical.

GELATINO-CHLORIDE PAPER.

CHAPTER III.

It is perhaps scarcely needful to say that before placing the gelatino-chloride paper in the printing frame, care should be taken to see that there is no damp lurking about either the negative surface or the pressure pads. Yet, in view of the very different nature of the soluble gelatine surface as compared with *insoluble* albumen, it may not be out of place to point out the necessity of a little more care in the matter than is requisite with ordinary silver paper.

With the latter, if sensitised at home, it is well known that unless perfectly dried before printing there is great danger of injuring the negative by silver stains; but so far as we have seen there is little, if any, tendency in this direction with the gelatine paper, owing to the minute quantity of free silver present in it. The danger comes wholly from the chance of the gelatine surface becoming glued to the negative, if there be damp influences to help it, and as, especially at this period of the year, there is always a certain amount of damp in the atmosphere, and the paper itself appears to contain a minute trace of hygroscopic matter—probably glycerine—it is well to reduce the risk to a minimum by attending closely to the

drying of the negatives as well as the printing pads, if they have been laid aside for any length of time.

In actual printing the paper will be found very much more rapid than albumenised when thin negatives are in question, but in the case of very dense images the difference is little, if any. The sensitive surface colours rapidly in the light, but soon reaches its maximum depth of tint and exhibits no appearance of “bronzing” in the shadows from over exposure the effect of which is simply to colour the lights without bringing about undue heaviness in the deepest shadows. Thus gelatino-chloride is eminently adapted for use with thin negatives, and will be found to give satisfactory prints from negatives which are quite useless with ordinary papers. But though suitable for negatives lacking force, it is by no means rendered useless for those which possess great density even to hardness, as might be expected, though here the increased rapidity in printing is not noticed. The explanation of this curious fact appears to be that the shadows of a “hard” negative rapidly reach their maximum of colouration, beyond which further exposure to light is incapable of moving them, and the lights and their half tones are thus allowed time to acquire sufficient force without heaviness in the shadows.

It is a question whether, after exposure, the prints require any washing previous to toning. The quantity of free silver present is so small as to interfere scarcely, if at all, with the action of the toning bath, and we have secured admirable tones by plunging the prints in the dry state directly into the toning bath. At the same time, for the sake of uniformity of action, it is better to pass the prints through at least one water before toning, as this will remove at least some of the slight acidity the paper exhibits; while the believers in thorough washing of albumen prints in order to remove all the silver previous to toning will, for the same reason, follow a similar course with the new paper.

The *débutant* with the gelatino-chloride paper must be prepared when he comes to the toning to entirely set aside his former notions of the process in connection with albumenised paper. Baths of the ordinary strength are no use whatever, as they simply discolour the print without altering its tone—as we understand the term. Nor is it possible to alter or expedite matters by warming the bath, except to such a point as will be insufficient to cause solution of the gelatine surface.

In very cold weather it may be permissible to slightly raise the temperature of the solution, bearing always in mind that the warmer it is the more tender will be the surface of the prints. Another difficulty lies in the erratic manner in which the image behaves in toning. Sometimes the change of colour will proceed as regularly, if not as quickly, as with ordinary paper, and the image will suffer little alteration in fixing. At others, though the apparent tone may be obtained as readily, it will disappear in fixing, and leave a hideous foxy-brown colour suggestive of fixing without toning at all. The best plan is to rely upon the colour the image shows on looking *through* the print; but even this is not an infallible guide, though after a little experience little difficulty will be experienced in securing regular tones of the desired character if the paper is at all capable, under the treatment to which it is submitted, of giving such tones. Warm browns, verging on purple, are easily obtained, and cool neutral greys give a very pleasing effect by carrying the action further. If this latter colour be appreciated, it is the safer and easier to aim for, since over action of the gold bath does not, as in the case of albumen prints, reduce it to the miserable blue tint so

common from over toning. To give enough time is what is required.

As regards the toning bath employed, it must be of greater strength than that usually applied to albumenised prints—even as strong as one grain of gold to two ounces of water. In the formula issued with more than one of the commercial papers a small trace of sodium hyposulphite is used, but we have been unable to detect any advantage in this addition, so prefer to discard it as a questionably useful and probably dangerous complication. The following is the best combination of many we have tried :

Chloride of gold	2 grains.
Sulphocyanide of ammonium	20 „
Phosphate of sodium	20 „
Water	4 ounces.

This is specially adapted to the cooler range of tones, but if the warmer class be preferred acetate of sodium may be substituted for the phosphate. The above quantity of solution will suffice for a sheet of paper of the ordinary size in the case of warm tones, and for about three-quarters of a sheet for the colder. Patience must be exercised in the operation.

Fix in a ten per cent. solution of fresh hypo for twenty minutes, and then transfer to a dish containing chloride of sodium (strength not very material) for another five minutes, then wash in the usual manner for three or four hours in running water, and finish off with a bath of chrome alum, ten grains to the ounce of water.

The surfaces of the prints are not particularly liable to damage during washing, though more tender naturally than albumen; but they require the greatest care in drying, especially in avoiding any application of heat. If required to be dried rapidly, after *thorough* “*aluming*” they may be “*dabbed*” surface-dry with a cambric handkerchief, and afterwards hung in a draught of cool air. They show little tendency to curl.

PROVERBIALY, November has the credit for being the darkest month in the year, but we think that, in the opinion of most photographers, to January should be awarded the palm, as this month usually eclipses the former for the most non-actinic light. This year January has been no exception, for, during an entire fortnight, the aggregate sunshine recorded at Greenwich amounted to three hours only. As a matter of fact, this amount was registered in one week—in the other it was *nil*. A profitable time this would have been for Metropolitan portraitists in the wet collodion days.

A CASE of interest to many is at present under investigation at the Bow-street Police Court. A charge of conspiracy to defraud has been instituted against certain individuals trading under different titles, as “The Decorative Art Institute,” “The Tint Oleo Company,” &c. By means of advertising, ladies have been induced fraudulently, it is alleged, to part with their money under the idea of eventually being able to earn liberal sums by painting Christmas and similar cards. It would manifestly be unfair to make any comments while the case is *sub judice*; but as the prosecution has been taken up by the Treasury we may rest assured that justice will be done.

It is truly surprising to note how frequently the system of rendering photographs translucent and then colouring them from the back has been resuscitated, and the high-sounding titles under which it has from time to time appeared. This method—originated in the very early days of paper photography—has been even patented over and over again. Large sums have also been realised by teaching this plan of colouring. With this no one would demur, provided the pupils who pay their money were confined to that class who can appreciate this

style of “art” and only desire to practise it as a pastime. Unfortunately, however, many needy ladies have often been allured by unscrupulous individuals into paying for tuition, under the idea that after they had learnt “the art” they would possess the means of earning a livelihood, in a genteel manner, by colouring photographs for the profession. After expending, perhaps, from two to ten guineas—often out of slender means—for tuition, and being pronounced proficient, the victims find that they have been grossly misled. This system of obtaining money is nothing less than a cruel fraud upon a comparatively helpless class, and is one upon which the Treasury will do well to keep an eye.

AZALINE, or azaline, which has been much inquired about of late, is one of the coal-tar colours. It is a nitrate of rosaniline, and is sometimes sold under other names—such as rubine, new red, fuschine, &c. It may be obtained from most dealers in aniline colours. This is not the same material as Dr. Vogel calls “azaline;” that, we believe, is a mixture of cyanine—the colouring matter of some flowers, such as the violet—and chinoline blue, the latter being the iodide of cyanine.

THE employment of eosine and chlorophyl, also colour screens, in connection with photographing colours, was practised more than ten years ago on, we may assume, a commercial scale. In 1876 M. Ducos du Hauron took out a patent in this country for improvements in photography, in which each of these materials are employed. Photographing through coloured screens, with tinted films, as a means of more correctly translating colour into monochrome, is not the novelty that many appear to imagine.

JUST now considerable attention is being paid to the question of the permanence of photographs made by different processes, and a great deal of ingenuity expended in devising crucial tests, with the idea of settling it, and thereby forestalling time—the real test. It is to be regretted that a similar amount of skill to what has, at times, been expended on finding out how prints may be caused to fade, has not been devoted to discovering the means by which those which have already faded could be restored. If such a process could be devised it would prove an exceedingly valuable one. Thousands of persons who have faded photographs of dear or departed friends, would be glad to pay liberally to have the prints restored to their pristine condition. Theoretically, the thing ought not to be impossible, seeing that, in the case of a faded silver print, all the material which originally formed the image still remains in, or on, the paper. It is all there, though its condition is altered. While every consideration should be given by experimentalists to making the photograph of the future as permanent as possible, it will give some attention to the restoration of those of the past. Here is an interesting problem to solve, and no doubt it will be some day, when great credit will redound to the solver.

PRACTICAL EXPERIENCE WITH THE ETHOXO LIGHT.

FOR a very long time, like many others, I looked upon this light with a great deal of suspicion, which I think was needless, for when the matter is investigated in a scientific way the whole affair seems simple, and I may say safe with *properly* constructed burners and apparatus, and with care I think little to be feared. The accident in Yorkshire I think deterred many from using it. I read the evidence very carefully, and to me it appeared gross carelessness. I often wonder there are not more accidents with the limelight than there are, seeing the reckless way some go to work. One of the chief causes I think may be attributed to things being done in a hurry (as regards preparation) at the last moment.

The first practical insight I had of the working of the ethoxo light was at the last exhibition of the Royal Cornwall Polytechnic Exhibition, at Falmouth, in September last, through Mr. Beard, Messrs. Oakley's representative. Being there officially during the whole week I had ample time to investigate it thoroughly. I then resolved to use the light myself, and had an ether tank made of the Hardwich-Oakley form, a full description of which was given in the pages of this JOURNAL some twelve months since, which was very explicit, but

at the same time there is nothing like seeing the thing at work in such competent hands as Mr. Beard's. I have eagerly read all I possibly could on the matter. Those saturators where a roll of flannel is saturated with ether I do not think sufficient to last for an evening's exhibition, and if there is any danger I think it would lie in running short of ether.

With the Hardwich-Oakley saturator, or tank, the size I have holds sufficient to last at least two and a half hours. In this saturator a part of the oxygen is passed over the surface of the ether, and there is no doubt about it becoming perfectly saturated.

There is another saturator I have seen described, being a kind of a wash-bottle arrangement, similar to that used for washing oxygen after it leaves the retort; with such an arrangement the light must be very unsteady on account of the bubbling. I have refrained from making any remarks upon this light until I had had it in use some time. The ether I use is methylated ether, s.g. 720. I fill the tank with it, or as much as it will hold without blowing out of the outlet tap when blowing through with the breath from the inlet tap. I place the tank close against the back of the lantern, using two short lengths of stout red rubber tubing for the connections with the side tubes of the lantern; when out of condition it does not cost much to renew them. When all is ready I open the inlet tap and the outlet which leads to the hydrogen side of the burner, and light up, to warm up the limes and condensers for a short time. There is one thing, the ether vapour must not be allowed to issue from the jet and escape, but must be lighted as soon as turned on, or the audience smell it at once and get alarmed (that is, some of the nervous ones). As soon as the limes are warmed the direct supply of the oxygen may be turned on in the usual way, and the result is a pure and brilliant light, according to the pressure from the bag or the bottle, very little inferior to the light given by the mixed jet—in fact, it is a mixed jet to all intents. I find that when using this light, if the slides are of a rich, warm tone in themselves, they will show the same colour on the screen. It is not always so with the ordinary mixed gases, for I have noticed, frequently, the coal gas supplied from one gas works will give a light of a reddish or yellowish tint, whereas the gas in another town from another gas works will give a light of a bluish tint—a light of the latter tint will make a warm-toned slide look inky black on the screen. This can be avoided with the ethoxo light.

The electric light for the lantern, however steady, is a mistake on account of its being so blue. I have put slides on that were perfectly claret colour, and on the screen they were as black as ink. But with the ethoxo light this anihilation of colour can be avoided. The tank that I have is made of stout sheet copper and tinned. When charged with fresh ether (that is, ether that has not been used for the purpose before) the light is pure, but if for another exhibition fresh ether is added to that remaining in the tank, the light will have a greenish cast on the screen, so it is as well to avoid it for the sake of a few pence. I have noticed that after an exhibition the ether that is left in the tank will throw down a white deposit. I have no doubt this may be a chlorine compound, perhaps with a trace of copper from the tank, which spoils the light. I have not yet had time to examine this deposit to see what it is. After the exhibition it is best to empty the tank at once and blow it out, and leave all the taps open for a time so as to get it perfectly dry, and use fresh ether for the next exhibition if you wish to get perfect results.

If using a biunial lantern, when the taps of the burners are once adjusted they do not require any further adjustment the whole of the evening, which is another great point in its favour; I also find, if a fair average lime be used, there is not so much pitting as with the ordinary mixed jet. I myself, like some other exhibitors, like the nozzle at such an angle to shoot a little up the lime, which is also an advantage against pitting of the lime. For this light the burners must be of special construction. In the ones I had specially made for me there is a pumice chamber just under the nozzle about half an inch deep, closely packed with crushed pumice stone that will pass through a sixty-mesh wire gauze, and will not pass through a forty-mesh, and it is astonishing how little resistance it offers to the passage of the gas, and I question very much if it is possible for the flame to pass back through it. In using this light there is no fear of unequal pressure as with the mixed gases; all coming from one bag or bottle any danger on that score is avoided. To put out the light, I turn off

the oxygen taps of the burners first, then the ether vapour, and then the taps on the tank, and finally the taps on the bag or bottle.

The light works steady and without the slightest noise with properly constructed burners, and without any variation the whole evening, and I think I may say without any more danger in careful hands. After the exhibition is over and the audience have left, blow out all the pipes, &c., at once.

There is one point that I have omitted, and that is, do not dissolve too quickly, or snapping will ensue, which had better be avoided. After the gases have been burning a short time the tank will be streaming with moisture; it might be alarming to the operator at first. It is owing to the evaporation of the ether in the tank, which rapidly condenses the moisture of the atmosphere on the cold metal. I think better results can be obtained with compressed gas in the iron cylinders than with the bag, and far more compactness, but with the bottle a governor *must* be used to keep equal pressure.

There is one thing that tells against the use of bottles, and that is the price, namely, eightpence per foot, which means a great expense for one evening. I think if a means could be found to reduce it to about one half that price it would be largely used. Carriage is an item, but I think that would be overlooked by the users if the gas was cheaper, as bottles save a lot of trouble. I believe the bottles could be returned by rail as empties to be refilled.

I for one would never make the gas if I could get it at the price named, as cylinders are less likely to wear out than bags; with the latter one never knows how soon they may give out.

WILLIAM BROOKS.

ECHOES FROM THE SOCIETIES.

At the present time, when the "Amateur question" is exercising the public mind to such an extent, it is painful to see dissensions creeping into the ranks of the oldest amateur society in the country, a society which has had a hitherto prosperous career of nearly a quarter of a century. Without discussing the details of the dispute in the Liverpool Amateur Photographic Association, there can be no doubt that a society which, by its constitution and laws, is essentially an amateur one, has a perfect right—nay, it is its duty—to exclude all members who may infringe the strict rules. But it does certainly seem to me that the proceedings in this particular case savour somewhat of inconsistency. Having winked at Mr. Ellerbeck's "offence" for some time, and actually on more than one occasion refused his resignation when tendered, it is scarcely to be wondered at that that gentleman should feel aggrieved at the sudden change of front, and more especially the manner in which the matter is brought forward. I speak purely on the facts as reported, without for one moment disputing the right of the members to expel one who is not an amateur. But it should have been done three years ago.

There is one very suggestive word in the report of the proceedings. It is stated that the action of the executive has become necessary owing to Mr. Ellerbeck's "*openly*" publishing his work. Are we to understand from this that the Liverpool Amateur Photographic Association permits, or encourages, its members to break its laws so long as they do it secretly? If so, I for one cannot help thinking that the Society is pandering to the very worst phase of modern amateurism.

In the course of some interesting remarks upon toning at the Cheltenham Photographic Society, General Dawson made a useful suggestion. Speaking of the necessity for very thorough washing of ready sensitised paper previous to toning in order to get rid of the acid contained in the paper, he stated that it is impossible to wash too much. Practically this is no doubt the case, but many operators in order to expedite matters, immerse the prints in weak carbonate of soda solution in order to neutralise the acid, and so render the toning more regular and reduce the expenditure in gold. This appears all right when the carbonate toning bath is to be employed, but it seems only reasonable that when the acetate bath is to be used a preliminary soaking in acetate of soda would be preferable, or in borax when that salt is to be combined with the gold. The salt employed in conjunction with gold in the toning bath exercises, as all know, a powerful effect on the tone produced; why not then the same effect if used as a preliminary application? If the warm tones usually obtained with acetate are desired, it is probable the object will be

partially frustrated by a previous soaking in carbonate, and the tones actually produced more closely resemble those obtainable with the latter salt. Not so, however, if the first bath be of acetate, as suggested by General Dawson.

At first sight it seems a curious discovery that was reported to the French Photographic Society by M. Franck de Villecholle, to the effect that the immersion of a plate in a solution of common salt, previous to development, acts as an accelerator. It is distinctly contrary to theory, since the first effect to be anticipated from treating a sensitive film with a soluble haloid would be to slow it. But on the principle that it is possible to get more out of an instantaneous exposure by using a developer containing soluble bromide than with one containing no restrainer, it is possible that salt employed in this manner may indirectly produce the effect claimed for it. The bromide in the one case checks any incipient tendency to fog, and permits the image to be "forced" to a greater extent than would be otherwise possible. So, too, with a plate of inferior quality, and exhibiting a tendency to fog under ordinary conditions, it is quite conceivable that a brief immersion in common salt, by restraining the fog, would produce an effect which might indirectly be described as acceleration, since with a given exposure a better and more vigorous development would ensue. I anticipate, however, that this result will only be obtained with plates of inferior quality, and that those which are originally perfect will not only fail to be benefited by it but will be actually retarded.

A question was raised before the London and Provincial Photographic Association as to the possibility of modifying platinotype prints by the addition of clouds and the like during the process of printing. I do not remember to have seen or heard this point raised previously; in fact, it appears to have been, to a great extent, overlooked by most amateurs, at least, who work the process. It is true there is a visible image produced under the action of light, but, as was pointed out by one of the speakers, it is so extremely feeble as to be of little value as a guide. It is not so much that the details of the picture are invisible, but it is the difficulty of accurately estimating the precise values of two portions of the image which, though in the undeveloped condition apparently possessing equal force, may when developed be found to be sadly out of harmony.

I can scarcely think the Chairman's suggestion of timing the various parts of the negative separately—I presume with silver paper—in order to get their respective printing values, will give much assistance in the matter. Assuming the values to be accurately taken, and that a uniform light enables the proper exposures to be given to each portion of cloud and foreground, there still remains the difficulty of dodging the joining, which, after all, is the chief one, and which requires the printer's close and careful attention. This is not a mechanical operation that a mere calculation of time, however correct, will effect, but requires the skilful treatment of a printer who knows his business. I do not mean to say—for I have had little experience with the process—that it is impossible, or even more than ordinarily difficult, to print clouds into platinotypes; but the subject is one which will bear ventilation, and those who have experience in the matter will confer a boon upon platinotype printers generally by publishing any hints which may be of value.

Apropos of a question asked at the same meeting with regard to the early experiments of Herschel and Hunt on the retarding effect of the red rays upon photographic action, I am reminded of an amusing argument I heard some time ago on a kindred subject between two enthusiasts, who waxed particularly warm in the course of the discussion. The question amounted to this, whether or not a feeble ray of white light filtering into the "ruby" room, had really the injurious effect attributed to it by most photographers. One of the disputants held that it had not. Without claiming the reversing action attributed to the red rays by many scientists, he argued that the ray of white light in penetrating the ruby-illuminated atmosphere of the dark room, practically passed through a coloured medium, becoming itself the same colour. His opponent held that this was "perfect rot," that the ray of white light simply "diluted" the colour of the illumination, and rendered it less safe than the original colour; that, in fact, the effect would be precisely the same whether the ray passed through a ruby-tinted space or a similar distance of absolute darkness. I don't think either convinced the other, or

ever would, and as to which of the two was right, it struck me that much depended on the size of the ray of white light and the distance it had to travel whether it was injurious or not.

In the discussion which took place at the London and Provincial Photographic Association, the Chairman mentioned Becquerel's conclusions, that the rays of higher refrangibility possessed reducing powers, while the red end of the spectrum exhibited oxidising or reversing properties. Coming closer to the present date, and to a practical application of the theory, I think reference should be made to Captain Abney's successful feat of photographing the infra red end of the spectrum in 1879 or 1880. The principle upon which this was done, was, I believe, precisely that mentioned; a plate already fogged by exposure to white light was acted upon by that portion of the spectrum where the red and invisible heat rays lie, and the reversing action of these formed the image.

A simple experiment with a luminous tablet of calcium sulphide will explain this action in a very clear manner. Let the tablet be excited by means of magnesium wire, and immediately placed behind a negative in a printing frame. Cover the frame with a piece of ruby glass, and again expose the whole to magnesium or sunlight. If the tablet be now examined in the dark it will be found to bear a positive impression from the negative, the red light passing through the shadows having quenched the luminosity in those portions. A still prettier experiment consists in exciting the tablet as before, and after it has lost its pristine brightness, allow the sun's spectrum to be thrown on to it by means of a prism. The effect is most remarkable. The upper end of the spectrum becomes brighter than the general surface of the tablet, while the lower end is proportionately quenched, and beyond the limit of the visible red completely extinguished for a considerable distance by the invisible heat rays. It does not require a great stretch of imagination to believe that what occurs with the phosphorescent tablet occurs also with the photographic plate. The experiment, however, is very easy to try.

There is possible danger to film negatives shadowed forth in the report of the last meeting of the Photographic Society of Philadelphia, where a member exhibited a negative which, originally $8\frac{1}{2} \times 6\frac{1}{2}$, had been enlarged to 10×8 by merely swelling or expanding it by immersion in water. If film negatives are specially liable to this expansion, it may be found of some inconvenience, but I can scarcely see why they, more than glass or paper, should be subject to separation of the film and support. We all know that if the gelatine film be detached from its support it will, when immersed in water, swell or expand to an enormous extent, which it will not do when the support is attached. But in the case of a "film" negative the support itself seems liable to the same sort of expansion. On the other hand, however, it should be remembered that as the finished film negative is stripped, *after drying*, from a glass plate, the image proper is never in the wet state allowed to trust entirely to the flexible support. If by any accident afterwards the negative should get wet, then the trouble would begin. Probably the recent substitution of collodion for gelatine for stripping may improve matters.

MONITOR.

BEAUTY OF POSE, PROPORTION, AND FEATURE IN PORTRAITURE.

[A Communication to the Edinburgh Photographic Society.]

In an old French book upon art, whose title and author I have long since most ungratefully forgotten, I remember reading a few chapters upon portraiture, in which likeness of pose, likeness of proportion, and likeness of feature were emphasised, in the order I give them, as the three chief desiderata in a good likeness. As the work to which I refer was written long before photography existed, and was read by myself when studying the rudiments of painting, I, at the time, saw little in the rules laid down, save that the characteristic action or pose of the subject should be broadly and thoroughly realised mentally before beginning to "block out" the proportions, and that this broad massing should, in turn, precede any elaboration of feature or detail. I was satisfied then of a fact which I had vaguely realised before—namely, that it was folly to begin by working from one feature to another in the hope that all would come right in the end; but it was not till I had taken up the art which we all mutually pursue that I fully understood the importance of a large preliminary view, for it was only then that I realised that in selecting and emphasising

what he considers the beautiful, and, at the same time, ignoring or subordinating what he looks upon as ugly, the power of the photographer is comparatively limited. When he makes what he acknowledges to be a mistake through forgetting that beauty, "grace, and, we may add, the likeness, consists more in taking the general air than in observing the exact similitude of every feature," he cannot rectify it save on a *rosa tabula*. Still, I do not see why the monochromatic "studies" of *mens* and lens should not please the beauty-loving eye better than the objective attempts at realism made by such of our brothers of the brush as have not yet found out wherein photography is capable, and wherein incapable, of taking the ground from under their feet. Setting aside colour, and tone implying colour, and also *technique* as referring to the visible evidence of handicraft, it will be found, I think, that the principles upon which the beauty of a single line is determined are applicable to every phase of criticism to which a picture may be subjected on its own merits.

To justify this statement, and thereby make my meaning clear, I would remind you that without light and shade together no form could be visible. And what we know to be true where form exists in absolute darkness, would be equally true were everything of the same brilliance. For instance, the form of the sun is lost to sight when the sky in the zenith is so bright as to dazzle our eyes. Since, under such conditions, we can have no visible form, we can have no apparent line. For, popularly speaking, a line is simply an empirical term applied to designate the impression of form conveyed by the interference of one density with another, under certain conditions of illumination. In this way we talk of the line of the horizon, a line of smoke, a line of soldiers, or a line of houses. It is only in this sense that we can speak of a line as visibly existing in nature at all. If the conditions obtaining here are equally to be applied to their artificial presentment on a plain surface, as I think they should—for what is a line of smoke beyond a charcoal line?—then, if we let a drop of ink fall on a piece of white paper, the blot will give the "line" of Euclid better than another drop which, instead of having been allowed to fall, has been regularly led over the paper with the point of a pen so as to copy the outline of the form assumed by the blot. Therefore, if when we speak of a line we acknowledge that we speak arbitrarily, and refer to what may be termed a cross between an invisible line and a visible superficies—or, in other words, as that which has length and breadth, and is visible—we would still have to acknowledge that the blot defined its own form and extent better than the copying outline, for in the outline we would have to decide whether it was its inner edge, its centre, or its outer edge which limited the magnitude. If Euclid's line be looked upon as the line of demarcation of two superficies, then the outline must necessarily cut off a portion of both or either. So, in everyday parlance, in speaking of a thick or even of a thin line, we refer to that which has breadth, and is not therefore the line of Euclid. And if we employ the term a "very thick" or a "very broad" line, we may be asked whether we would consider as a line at all a very short line drawn with a very broad pencil, so as to form a square. And if we were to reply that a square mark was not a line, and a fresh mark were made by a still shorter stroke from a broader pencil, what would we say then? Are these marks lines, points, or superficies? What is a line?

Now as I want to talk about art, and not about mathematics, I will ask you, for my argument's sake, to allow me provisionally to define a line as any mark whereby more or less isolated and fractional form is visibly indicated, a compound line being a series of salient and somewhat disjointed marks.

Composition, disposition, position, and pose, differ only in degree. They all mean arrangement, and the first mentioned includes all the rest. Composition will not allow us to deal with the position of a man as a thing of legs and arms, save after we have determined the disposition of himself and his surroundings with regard to the shape of the enclosing space wherein he is to be posed or placed. Neither will it allow us to deal with the direction of any curve or line of direction, or leading line, no matter how important, until we have roughly settled the disposition of the masses of light and shade which I wish for the time being to call principal lines (points or regions) of position. But in so far as the supposition of the existence of the smallest line gives rise to many points, so inversely from the multiplicity of these lines of position there is formed at last one line of direction, the principal line of all. With it, then, we have first to deal.

But let us see that we have thoroughly realised its existence. The eye involuntarily goes straight to the region of greatest contrast, and where a number of salient patches of strongly contrasted lights and shadows congregate, there must the eye wander. If these patches (lines of position) are all approximately of the same brilliance, size, and shape, our glance roams restlessly to and fro in search of some point of attraction greater than the rest, and if none be present, which

will possibly be the case where the lines of position have been allowed to fall at random, it will seek to discover some constellation, and, having found one, will then go jerking backwards and forwards among the points like a weaver's shuttle, laboriously and vainly striving to gyrate among them, instead of dashing about like a newly-caged bird struggling to escape.

Though somewhat mixed, this metaphor allows us very easily to form an idea of the different way in which the eye will be affected by a picture of a nice, clean, long, straight broomstick, standing erect, as opposed to the feeling produced by the contemplation of an Oriental willow-wand reposing.

Possessing some thought which he deems worthy of being embodied in a picture, the first aim of the artist is to subordinate the brilliance, size, and shape of the lines of position and direction so as to admit of the formation of one leading broad irregular, and somewhat disjointed curve composed of them all.

His next thought is where in the space he has allowed himself he shall place this curve. This he will determine by the place in this principal line of direction occupied by the principal line of position; which must be that possessing the greatest contrast in portraiture—the head or a part of it—and, by its salience, considered in relation to other points of minor interest. This line he places near the centre, and to the right or the left, as the exigencies of the occasion may require, but always above the centre. How far above will depend upon how much of the body is seen, and whether an arm forming a line of direction, or affording a line of position in the principal curve, rises above the head. In dealing with a bust, for the same reason, where the face, the principal line of position, is fronting the spectator, there will be little variation in the amount of space on either side, but when in profile the additional attraction given to the eye necessitates a greater amount of space in front of the face than behind the head; this is simply equivalent to placing the principal line of position where it was before. In the same way, if the face is looking in one direction and the body is turned in another, the principal line of direction will suggest a curve like that of the letter S, and the entire head will again be brought nearer the centre to allow the principal line of direction (S) to occupy its true position in the enclosing space.

Parenthetically, since I have made use of one letter of the alphabet, I may as well give a list of the letters and figures which, classed according to their suitability, and want of suitability, to form principal lines of direction, I once drew up in illustration.

1. Suitable types:—

G Q J S, c s g a e t f, 9 6 2 5 3, & ?.

2. Unsuitable types:—

T X K E L I O, 8 4.

The remaining letters and figures are either repetitions of those already used, are inapplicable as tending to confuse, or else, like A, V, W and M, imply a treatment of composition foreign to that in hand, and, to my mind, less simple (I refer to the pyramidal scheme). The sign indicating the bass clef in the musical staff is perhaps the most suitable of any, and the sign indicating the treble is certainly the most beautiful. As I have stated that the arrangement of the disjointed principal line of direction, and its relations to other minor lines of the same kind and to lines of position, can be inferred from the fundamental laws which define the beauty of a single simple line, I will postpone further consideration of the most suitable curves it may assume till I come to touch on beauty of feature. One fact of extreme importance should, however, be noted: the principal leading line must—absolutely must—return into itself, *e.g.*, c & s.

The artist who illustrated *A Trip to Blunderland* showed me one day a piece of paper covered with attempts to fulfil the author's wish, and to illustrate the entry of some character—a herald, I think—as "a point of interrogation!" I have not seen the book, but, if the finished design is as clever as the sketches were, I will back that pose against that of a man standing at "tention!" for beauty of line.

(To be continued.)

HUGH BRENNER.

PLATINUM PRINTS.

THE recent yellowing of certain platinotype prints under the action of sulphur, as described in these pages by Mr. Andrew Pringle, indicates that the subject ought to be investigated to the roots by those who do not care to print from their negatives at all unless they can get pictures likely to last for a few centuries at least, and by all those who feel that moral obligations rest upon the present race of photographers to adequately perform their duty as pictorial historians working for the benefit of posterity. The loss to the world of the

otherwise historical records which have faded from the surface of albumenised paper within the present generation is now irreparable, and even in the region of private life in nearly every house may be found some pea-soup looking blotches upon paper, over which the possessors mourn as all they have left to remind them of the features of a member of the family who a few years since departed this life. When a bootmaker sells boots which fall to pieces in a fortnight, the remains of those boots are not preserved in moreoco shrines for years for exhibition to all comers, the more is the pity; but when a photograph rapidly fades, what is left of it is fortunately preserved as long as possible, and has the name of the issuing firm upon its back. Probably the prevalence of these yellow failures in British homes has something, but not all, to do with the present bad trade and low prices in photography. It would be well if there were more imitators of Messrs. Gêrûzet Brothers, of Brussels, who for about fifteen years past have not sent out a single photograph likely to fade during a few generations; all their work, large and small, has been done in carbon, consequently many an album in Belgium must now practically testify to its possessors the efficiency with which Messrs. Gêrûzet have done their duty.

To platinum, however, the relatively imperishable nature of which is well known, must all photographers turn in relation to work intended to be of historical value, and if once any one could definitely prove anything against its character for permanency, the fact would be lamentable in itself and detract from the importance of the whole of the various platinum processes. Mr. Pringle found certain platinum prints to turn yellow under the sulphur test; Mr. John Spiller had the same experience several years ago, and it was then explained that the fault was due to the presence of a salt of lead in the commercial sample of paper, the use of which salt, it was subsequently announced, would be discontinued in its manufacture.

In the early days of the history of photography Sir John Herschel discovered that the presence of the salts of lead greatly facilitated the reduction of the salts of platinum by light. In Willis's first patent, dated June 5, 1873, the sensitising solutions for his platinotype paper are described as one part of chloroplatinate of potassium in forty-eight parts of water, applied to the paper and dried; next the paper was treated with one part of nitrate of lead in forty-eight parts of water, and dried; then it was brushed over with one part of ferric oxalate, in eight parts of water, acidified with oxalic acid. Hence the finished sensitive surface contained as much lead salt as platinum salt, for which latter silver nitrate was sometimes substituted, accompanied by other modifications of the process.

In his next patent, dated July 12, 1878, he reduced the proportion of lead, and employed:—

Water	30 parts.
Chloroplatinite of potassium	1 part.
Ferric oxalate	4½ parts.
Lead chloride	0·13 part.

In his third patent, dated March 15, 1880, he proposed to abolish the use of lead altogether, as well as of the silver salt which he sometimes used in place of lead, and gave the following formula of his sensitising solution:—

Water	30 parts.
Potassium chloroplatinite	4·2 "
Ferric oxalate	4·2 "

With the presence of traces of silver in the whites of the image one can easily see how yellowness would result from the sulphur test, or with the presence of lead how a darkening would take place which might loosely be described as "yellow;" but as persons buy platinotype paper for the sake of permanency, and to get rid of such unstable substances as salts of lead or silver in contact with organic matter, were Mr. Pringle's experiments done with prints taken before the issuing of the 1880 patent? If not, what is the cause of the yellowing? The matter should be thoroughly investigated, because if his charge could be substantiated against prints taken by all platinotype processes, their chief *raison d'être* would be demolished; the amount of their permanency would then be a matter of argument and question, instead of—as Professor Dewar assured the Royal Institution a few days ago—being an indisputable fact. Platinum would, however, still have the credit of giving more refined and artistic results than silver does upon albumen, despite the fine detail of the latter class of pictures. The collodio-chloride process, however, can be made to give finer detail, a better surface, and more permanent prints.

I have often thought that every photographic society should permanently keep a stock of standard solutions, such as those used by Mr. John Spiller for testing platinum pictures, and when prints by any new process are produced, one of them should be cut up and the strips be immersed during the evening in test-tubes containing

the solutions. Some prints would disappear in no time under tests which platinum would easily bear; such disappearance would not necessarily prove the prints to be valueless, but would give useful information forming a subject for discussion. The blue prints by the iron processes are destroyed readily by alkaline solutions, even when very weak, yet under the conditions incidental to the keeping of diagrams in engineers' offices, it is known that blue prints have much permanency—in fact, the blue darkens a little with age; at the same time there is no harm in knowing what particular agencies are most prone to damage particular classes of prints. Such tests would not give exact information as to the relative durability of the prints by various processes, but the results obtained would be suggestive in that direction. Were more regular work of general public interest such as that now suggested taken up by the photographic organizations, their influence would be increased, and the possession by each of them of a good lending library of scientific books would be as great a factor in bringing in new members as it proves to be in societies connected with other scientific subjects. A reading room containing all the photographic journals would be attractive; at present the Photographic Society only lays upon its table one periodical printed in the French language. If the refined and intellectual French nation were to be blotted out of existence to-morrow, the members of that Society would not be a jot the worse so far as concerns their present associated facilities for reading the photographic literature of that country.

The solitary periodical in the French language laid upon the table of the Photographic Society is the *Bulletin Belge*, printed in Brussels. This is, in my opinion, the best of all the existing monthly periodicals connected with photography issued in any part of the world. It is well got up, and at considerable expense it has for a long series of years published in every issue a frontispiece illustrating some photographic printing process, confining itself of late years to the more permanent classes of pictures, thus making a historical record of the progress of printing processes. Captain Abney is its English correspondent, and contributes frequent articles on the progress of photography in this country. The photographic periodicals from all parts of the world are carefully examined by its managers, and every month it prints brief abstracts of all it finds in them of most value. In all the periodicals printed in the French language, nothing personally offensive or calculated to annoy any one is ever published, and as such things are not inserted, the editors are probably not troubled with communications containing paragraphs of that description. No doubt the fact of the average popular education being five or six times higher in the more civilised Continental nations than in England has something to do with this refined atmosphere of literary respectability. The *Bulletin Belge* once printed Dr. Van Monckhoven's claim to be the originator of the platinum process, and to have discovered that platinum prints fade. I looked up his past utterances by means of the references he gave, and found that they did not substantiate his claim to priority; moreover, his statements about fading are unsupported by any other experimentalist. Captain Pizzighelli and Baron A. Ifubl made a like investigation of his statements, and with the same results.

PATENTS COMPLETED.

IMPROVEMENTS IN THE FORMATION AND CONSTRUCTION OF PHOTOGRAPHIC CAMERAS.

No. 2670.—JOHN EDWARD THORNTON, New Lorne-street, Moss-side, Manchester.—*February 24, 1886.*

THE improvements which are the subject of this invention, relate to the form and construction of photographic cameras, and the object of my invention is to effect a reduction in the weight of photographic cameras, by the avoidance of accessories and external requirements, or replacements of duplicates and loose parts.

In constructing a photographic camera according to my invention, I form the baseboard with an aperture or opening, the object of such an opening being for a twofold purpose, hereinafter more definitely described; firstly, for forming a receptacle for the lens or lenses; and secondly, to serve the purpose of a tripod head.

The front board or panel to which the lens is usually attached, I form of the ordinary shape externally, but with a circular opening of a suitable size through the centre. I fit into this opening a revolving panel or table, to which one, two, or more lenses are attached, in such positions that, by revolving the said table, either one or other of the lenses, as required, may have a central position, and come opposite centre of plate. The front board is supported between struts in the usual way, and with sufficient rise and fall to allow one of the lenses attached to the front board being placed opposite centre of either upper or lower half of plate. By these means a lens of the size required may be used without detaching the unrequired sizes of the lenses from the camera, and thus remains always complete and ready for use.

When the operator desires to pack the camera, the front board with the lenses affixed, is laid down on the baseboard, the opening in the baseboard forming a receptacle and packing space for the lenses, thus obviating the necessity for their removal from the front board.

In order to retain the Kinear form of bellows, I make a slight extension on the upper side of the first two or three laps.

To the edge of the circular opening in the baseboard I attach, firmly and permanently, a hollow or box-shaped metal ring, with a groove or opening in the said ring: this groove in the fixed metal ring forms a receptacle for the upper ends of the legs supporting the camera, around and upon which the camera revolves. The upper ends of the legs are retained in their position in the fixed metal ring by a spring or other suitable means.

The standards between which the front board is supported are hinged at their lower ends to a transverse bar. This transverse bar is made with V-shaped, or other similar suitably formed ends, which fit into corresponding recesses in the sides of metal racks attached to baseboard, so as to place the front board nearer to or further from the camera body for long or short focus, as desired. These racks are formed with teeth both on their upper and lower sides. A pinion working in the teeth on the upper side of racks causes the transverse bar, carrying front board with lenses attached, to travel backwards or forwards, and a pinion working in the teeth on the under side of racks operates the sliding frame of baseboard in a similar manner.

When it is preferred to draw out or close the baseboard quicker than by operation of rack and pinion, I withdraw the pinions from contact with the racks by transverse pressure on the pinion spindle, and the baseboard may then be drawn out or pushed in by hand: the pinions regain their previous positions by means of a spiral spring, which retains them always in gear with racks except when purposely displaced.

In a central position, on the under side of the camera body, I attach a plate in which I form a transverse slot: through this slot passes a set screw: the camera body may obtain a lateral movement and also the required horizontal swing, and be held firmly by means of the said set screw.

In the place of the ordinary ground-glass, I use, as a focussing screen, a suitable translucent material wound on a spring roller, which is fitted on one side of aperture of camera body; the method of using this focussing screen is the same as an ordinary spring blind, being held at one side by a fastener when required in use, and winding itself on the roller when released.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at a meeting of the above Society, held at 5A, Pall Mall East, London, Mr. William England, Vice-President, occupied the chair.

Mr. DIXON exhibited some of his specimens of orthochromatic prints and negatives. He said that after many months of experimenting he and Mr. Gray had worked out the process; among the facts which had struck him was the wonderful way in which the process made old pictures come out like solid objects; of this he could give no explanation, but he exhibited copies of old paintings taken in the National Gallery to illustrate his statement. In the process they used some chemicals named by a patentee, also some not named by him; some of the commercial plates in the market answered for the purpose and others did not; they were rendered orthochromatic by dipping in a bath and drying; Edwards's plates were excellent for the purpose. The keeping qualities of the finished plates were doubtful; some were as good as ever after the lapse of six or eight weeks, others went bad in two or three weeks; their rapidity was doubled by being achromatised, but when they

were used with a yellow screen the normal exposure of the plates had to be quadrupled.

Mr. J. CADETT said that Mr. Leon Warnerke had told him that ordinary plates, if used with certain kinds of yellow glass, would give almost as good results as certain specially prepared orthochromatic plates; to the eye several of these yellow glasses looked just the same, but worked quite differently when used in the photographic operations, therefore the sample of yellow glass for orthochromatic work should be specially selected.

Mr. J. TRAILL TAYLOR asked if any one had tried cyanine, the colouring matter of the violet, as a substitute for eosine in the preparation of orthochromatic plates.

Mr. W. M. ASHMAN responded that two years ago he had used alcoholic extracts of the colouring matters of various garden flowers, and had exhibited the results to that Society; it was admitted at the time that improved negatives had thus been obtained by him; among the colours he tried were those of the sunflower and of the common French marigold.

Mr. B. J. EDWARDS was pleased to give Mr. Dixon credit for what he had done in introducing the process to the notice of photographers, but it had previously been worked out and brought into every-day use on the Continent; the details, moreover, had been published more than once in this country. The case reminded him of a man who found a plough forgotten and neglected in a corner of a field, so took possession of it and used it, but it was not the finder's plough, for it belonged to somebody else all the time. The speaker here exhibited some orthochromatic photographs, several of which had been taken four years ago; one of them was Murillo's *Virgin of Seville*, which he said was a painting which it had long been thought to be impossible to copy by photography, but was at last obtained by means of one of Clayton & Tailfer's plates. The process was excellent for ordinary photographic work, and, among other things, was good for snow scenes. Tailfer's patent was published in this country on the 8th of January, 1883, and the process was described in *The Journal of the Photographic Society* of April, 1886; full instructions for preparing the plates were therein given, so there was really no secret in the matter at all; there was no difficulty about it beyond that of getting the proper eosine, for twenty-five or thirty kinds of eosine are known, and Dr. Vogel had stated that it was impossible to get a pure one in the market. A solution of the proper eosine had to be made—it should be strong enough to be of rather a deep pink colour; the plate had to be dipped into it, then washed under a tap and dried, and the whole thing was done; the only trouble was that the plates so made would not keep. His own plan was to make the emulsion orthochromatic in the first instance, and he could produce plates which would keep for years; the plates were not slower than ordinary plates or in any point inferior to them, consequently Tailfer's discovery was a great advance in photography. Mr. Dixon had mentioned that it was the subject of a patent, but if a Frenchman took out a patent in this country his rights ought to be respected; Tailfer had not been able to obtain a patent in Germany, so there the process was free and open, but not so in Great Britain. He (Mr. Edwards) had worked at orthochromatic photography in the attempt to "get round" Tailfer's patent, but it checked him at every turn, so but two courses were open to him—either to steal it or to buy it, and of course he did the latter. M. Tailfer had written to him asking that he would inform the Photographic Society and the public that he did not claim in his patent the application of eosine to photography; he claimed solely its application to the gelatino-bromide process. At the time of the discovery this was believed to be impossible, and such had been stated in print, so he (M. Tailfer) thought that Englishmen ought to give him credit for what he had done. A silver medal had been granted at the late Inventions Exhibition to M. Tailfer for his specimens of orthochromatic photography without a yellow screen, and one had recently been given by the Photographic Society to Mr. Dixon; he (Mr. Edwards), thought that M. Tailfer ought to have had both.

Mr. W. BEDFORD knew many photographers who, like himself, had tried Tailfer's process as described in his patent, yet failed to get the results, and until Mr. Wellington published some distinct formulæ a few days ago, including the use of free silver, he had been unable to succeed. It had been said that the use of a particular variety of tetrabromide of florescine was necessary. Perhaps some chemist present could tell them something about it.

Mr. EDWARDS responded that he never used free silver.

Mr. TAYLOR suggested that any one present, versed in patent law, should tell them whether a patent, to be a good one, should not so describe the invention that any skilled photographer would be able to follow the instructions and work the process successfully.

Mr. EDWARDS could bring three who had succeeded; he did not know how many had failed.

Mr. TAYLOR responded that that raised the question whether Mr. Bedford was a skilled photographer.

Mr. EDWARDS said that it had been found that the only way to make a valid patent was to include the whole eosine group, for it could not be otherwise described.

Mr. DIXON asked how a man could claim what he could not describe? The results which he (Mr. Dixon) had exhibited that evening were ten thousand times better than those exhibited by Mr. Edwards.

Mr. EDWARDS remarked that in some of those spoken of by Mr. Dixon a yellow screen had been used in the camera.

Mr. FRIESE GREENE said that if Mr. Dixon had not greased and oiled the old plough, perhaps Mr. Edwards would not have taken it up; Dixon's were evidently the best plates which had yet been placed upon the market. He (Mr. Greene) had sent some of his orthochromatic results upon collodion to Sir Henry Ponsonby, who had exhibited them to the Queen.

Mr. WOLLASTON said that at that Society they had to deal with results and with scientific effects, and not with questions of patent law. He had produced orthochromatic photographs ever since Clayton & Tailfer's plates appeared in the market. He here exhibited some specimens, one of them, he said, being a subject with which good photographers had hitherto failed to get results at all. He gave ordinary exposures, and applied ordinary developers, but he was obliged to go back to the old ruby light in the developing room.

Mr. W. E. DEBENHAM exhibited the results of his orthochromatic photo-

graphic results with the popular picture, *Sweets to the Sweet*. He had used eosine, and a yellow screen produced by coating the inner surfaces of his lenses with collodion containing eosine; he thus avoided extra reflections, and adverse optical effects liable to be introduced by plain glass screens. One of his yellow screens, however, was made of two discs of extra-white patent plate, each coated on one side with collodion containing aurine; the coated sides were then cemented together with Canada balsam, so that the yellow film was protected from injury, and the compound disc could be easily cleaned. Old pictures were usually very yellow, whilst the cracks in them reflected much white light, but the yellow screen toned down the latter, and therein he thought was the explanation of the problem of the exceptional appearance, mentioned by Mr. Dixon, of old pictures in orthochromatic photographs. Mr. Edwards claimed the use of eosine in conjunction with ammonia; his (Mr. Debenham's) plates were prepared without ammonia. He did not think that he had ever seen the reds so well rendered as by Ives's chlorophyl process. The German Government always made inquiries before granting patents, and when a discovery was not new, no patent was granted; it was desirable that some such system should be adopted in this country, in which a patent had been defined as "a right to go to law."

Mr. DIXON said that he could double the rapidity of ordinary plates, and had exhibited that evening the result of a comparative experiment.

Mr. EDWARDS stated that the speed to pure white light could not be increased, but some time had elapsed since pure white daylight had been seen in London. Mr. Dixon should test with the light of the sensitometer tablet.

Mr. INCE asked if sensitive paper films could be made orthochromatic.

Mr. HYSLOP replied that there was no difficulty whatever in doing so.

Mr. JOHN SPILLER, F.C.S., said that he had had some of the responsibility of awarding the medal to Mr. Tailler at the Inventions Exhibition of 1883, for he was then one of the jurors, and had as colleagues the late Dr. Diamond, Dr. Warren De La Rue, Colonel Stuart Wortley, Captain Abney, Mr. Bolas, and Mr. Bolton, all members of the Photographic Society; so he thought that in the multitude of counsellors there was wisdom, and that Messrs. Clayton & Tailler deserved their medal. They claimed the use of the eosines in conjunction with ammonia and alcohol, the latter being not altogether indispensable. The patent gave a fair description of what was known in commerce as eosine, and he thought that nobody could use eosine for the purpose but the owner of the patent. Eosine is made from fluoresceine combined either with chlorine, bromine, or iodine, or sometimes some of the nitro group are introduced. Mr. Edwards, he was informed, used tetraiodofluoresceine, a substance which might give a cross action upon a gelatino-bromide plate, as in the example of washing such a plate with iodide of potassium. It might be that there were differences in some of the eosines, but any eosine would answer the purpose to some extent, otherwise the patent would be invalidated. Mr. Edwards said that tetraiodofluoresceine answered best. That could always be obtained of perfect purity, and all samples always alike.

Mr. W. T. GOODHEW showed that by varying the development he had produced more orthochromatic results than the ordinary plates otherwise gave.

Mr. DEBENHAM pointed out that at the same time some other parts of the picture had been deteriorated. He thought that a plate made more sensitive to yellow light must be more sensitive to white light as a whole, as the latter contained so much yellow.

Mr. EDWARDS said that the enhanced sensitiveness was very small. He exhibited a coloured screen made by placing a disc of yellowed gelatine between two pieces of metal of the form of a lens stop.

The CHAIRMAN thought Mr. Debenham's plan of colouring the lenses to be admirable.

Mr. W. F. DONKIN remarked that the plates had been called both "orthochromatic" and "isochromatic," the former of which he thought to be the correct rendering, for the former meant giving the results truthfully, and the latter giving everything alike—everything an equal smudge—at least that was the idea which the word conveyed to his mind.

Mr. DIXON said that if he went to any chemist and asked for eosine, he would not give him the substance with which he prepared his plates, which plates, he maintained, were distinct from all prepared with eosine.

Mr. EDWARDS stated that Mr. Dixon's plates had been tested and found to contain eosine.

Mr. DIXON responded that it then "must have got in on the sly," he did not put it in. However, he would no longer sell the plates, as he would not risk the uncertainties of the law. The orthochromatic results he had exhibited had not been equalled in London.

Mr. SPRUCE said that at the next meeting of the Society he should partly deal with the subject of that evening.

A vote of thanks to Mr. Dixon, for bringing the subject under the notice of the Society, was moved by Mr. J. Sebastian Davis, seconded by Mr. Edwards, and carried, after which the meeting broke up.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday, January 13, a kind of scientific entertainment took place under the auspices of the above Association at the Masons Hall Tavern, City, London, with Mr. J. J. Briginshaw in the chair. There was a large attendance, including a considerable proportion of ladies.

Mr. Watson, of Holborn, exhibited a number of scientific instruments.

By means of the optical lantern various photographic views were projected upon the screen, and changed by means of Mr. J. B. B. Wellington's lantern slide changer, which blotted out the light automatically for a moment when each change was made. One of his views, representing Haddon Hall, drew general applause from its enhanced pictorial beauty caused by the inclusion of natural clouds instead of the usual bare sky. Among the other lantern pictures projected were some by Mr. L. Medland of animals in the Zoological Gardens; some by Mr. Briginshaw, of photographs of insects; some by Mr. J. Hubert, also of insects, of which he likewise exhibited live specimens; and some slides by Mr. F. P. Cembrano and by Mr. Kingdon. Mr. York's American and Canadian views were instructive and interesting.

Music, songs, and recitations were given by Mrs. Briginshaw, Messrs. Cripps, Herbert Starnes, H. A. Bridge, and W. Cobb, after which the company parted, highly pleased with their experiences.

CAMERA CLUB.

On Thursday, the 20th instant, the subject under discussion was *The Development of Bromide Paper*, opened by the reading of a communication from Mr. Andrew Pringle. Dr. J. Foulerton occupied the chair.

A large number of film negatives and positive prints, sent by Mr. Pringle to illustrate his remarks as to the capabilities of bromide paper, were handed round for exhibition.

Mr. KIDD said his experience tallied in most respects with Mr. Pringle's, but he did not advise the use of an excess of bromide to give density. A small amount of bromide gave best results, a better colour particularly. Increase of bromide caused a brownish green colour. If from over exposure a great addition of bromide became necessary, that print would not be of much use. With a dense negative a smaller proportion of iron to oxalate should be used. He did not use acid after development, but found a plug of cotton wool, if used skilfully, and with all thoroughly in soak, rubbed off the developer and prevented precipitation of lime in the paper. As the original introducers of the bromide paper, his firm had at first found the black colour much objected to, now nothing but engraving colour photographs would be looked at. The colours given by albumenised paper were not approved by artists and people of cultivated tastes.

Mr. HERBERT FRAY said he thought great care was needed in getting rid of the acid before fixing, as a very injurious sulphur action might be set up in the fixing if acid remained in the print. The acid bath was not absolutely necessary. He considered that it was important that development should be prompt, and that bromide be not used in excess if soot and whitewash effects were to be avoided; also, that in exposure distance from the light should be carefully considered and regulated by the strength of the light and the density of the negative.

Mr. ALFRED HARMAN said that the acid bath was absolutely necessary to prevent the precipitation of oxalate of iron in the pores of the paper. The picture, too, was more brilliant from the acid treatment. He then made some interesting remarks on Alpha paper. It was slower than bromide ordinarily, but gave great range of colour. When the objectionable greenish colour came it was a sign of no toning action.

Mr. WALKER agreed that the acid bath was needed, at any rate, in America. He had intended showing some sensitometer tests exhibiting density curves, to rebut the assertion that half tones were not obtainable on bromide paper, but had been prevented carrying out his full intention. Some prints by M. Nadar, of Paris, showing every gradation and great detail in the shadows, were exhibited.

Dr. FOULERTON preferred to use magnesium wire in exposure rather than paraffine or gas, and he placed his printing frames round in a circle, exposing all together at one illumination.

Mr. FERRERS said he also preferred magnesium wire, as giving more even tone, but found that exposing in a circle caused objectionable reflections across from one negative to another.

Mr. DAVIDSON, referring to Mr. Kidd's remarks, thought that it was the glaze rather than the colour in albumenised paper prints that was objected to by artists, or by anybody who looked for "quality" in pictures, and that photographs on plain salted papers and papers of matt surface generally rendered the feeling of a subject much more effectively than the ordinary albumenised paper. Colour was a matter of taste, but he preferred a warm coloured print when it was not crude. For this reason he went greatly for Alpha paper. It did not, in his hands, appear to give a certainty of obtaining warmth, though a grey could be got at will. He found his toning bath had to be much stronger in gold than that recommended or else the greenish appearance remained.

Mr. W. H. WHEELER said he found, from his experience amongst artists, that the colour of a monochrome was a matter of individual taste, the glaze of a silver print being the point of objection. Etchings of a brown colour were now highly appreciated, and a painter in doing work in monochrome greatly used sepia.

Mr. H. H. O'FARRELL said he personally did not like the warm tone either in prints or in discussion, but supposed it was all a matter of taste. Referring to a point in Mr. Pringle's paper and to one of the negatives handed round, he said the opinion of himself and many in the room was that it was not by any means a dense negative, as claimed by Mr. Pringle, but just such an one as would give a good print on any paper.

Mr. D. P. RODGERS said that also was his opinion, and he still thought that bromide paper required a thin negative rather than a vigorous one. Different makes of paper seemed to require different methods of treatment; acid was required with one maker's and not with another's; if he had a thin negative he used Messrs. Eastman's paper, if a dense one, Messrs. Morgan & Kidd's or Messrs. Fry's. In regard to colour, he had obtained a fairly warm colour on Eastman's bromide paper by the use of a soda developer. On Alpha paper he had secured, without toning, all shades between red and black by altering the developers. He would suit colour to subject—a snow scene in black and white, a sunny scene in warm colour.

Mr. H. J. GIFFORD said he would like to know what was the composition of the developed image in the argentic bromide prints.

Great interest was excited by the exhibition and working by Mr. Spiekernell of one of Messrs. Marion's (Urie's) automatic printing machines.

Votes of thanks were passed to Dr. Foulerton and to the visitors who had contributed to the interest of the evening.

The subject for Thursday, February 3, is *Artistic Photography*. Paper to be read by Mr. W. H. Wheeler at eight p.m.

MANCHESTER PHOTOGRAPHIC SOCIETY.

The monthly meeting of this Society took place on January 13, 1887, at 26, George-street, Manchester.—The President, Mr. Arthur Coventry, in the chair.

The minutes of the previous meeting were read and passed, and the following gentlemen unanimously elected members of the Society:—Messrs. G. H. Rigby, Albert Woodbury, J. L. Barker, J. Hart, and N. Smallpage.

The PRESIDENT reminded members who intended exhibiting at the Jubilee Exhibition in Manchester that space must be applied for this month, and also that all exhibits must be framed. The Council of the Society had decided not to apply for any space as a Society.

Mr. A. BROTHERS, F.R.A.S., then gave an address, of which the following is the substance, on the *Progress in Astronomical Photography*. He said, I shall pass over the early history of the subject in a very few words. I can do this very safely because, in December, 1865, I read a long paper before the Photographic Section of the Literary and Philosophical Society on this subject, which was printed at length in the *Proceedings* of that Society, also in THE BRITISH JOURNAL OF PHOTOGRAPHY, the *Photographic News*, ten years later in the *English Mechanic*, and in two editions of *Chambers's Astronomy*. In compiling the paper I went into the subject very fully, and gave an account of what had been done up to the date named. Since 1865 a good deal has been done in America, where there are many observatories where photography is practised. Amongst others, Mr. Whipple photographed stars, and the experiment was tried on the star α Lyre. At that time only the brightest stars could be photographed, as only the Daguerreotype and collodion processes were available. In 1867 Mr. Bond photographed the double star ζ U. Majoris, the time occupied being eight seconds. Mr. Rutherford, another very eminent astronomer in America, turned his attention to photographing stars as well as the moon with his telescope of thirteen inches aperture corrected for the chemical rays. His plan was to make a photograph, then allow the telescope to remain still for a few seconds and then take another picture. That is a good plan, and in the days of photography when spots were more prevalent than they are on gelatine plates it was absolutely necessary. This would be all very well in photographing a few stars, but would be useless at the present day. Having succeeded in photographing stars, the next subject which occupied the attention of astronomers, chiefly in America, was that of photographing the nebulae. These, relatively to the bright stars, are very faint objects indeed in the telescope. To photograph them in those days with the most sensitive surface they could employ was almost an impossibility. Mr. Draper, in 1851, had succeeded in doing it. An astronomer went from America to Cordoba for the purpose of mapping the stars in the southern hemisphere, and after doing that turned his attention to photographing them, and succeeded to a great extent. In England the Rev. Mr. Espin, sometime resident near Liverpool, gave this subject his attention. His main object was to form a means of estimating the brightness of the stars, and in this he was partially successful. Next we have Dr. Huggins, who has done much in the application of photography to astronomical purposes. He has done more in photographing the spectra of stars than anyone else. He also had an idea that it would be possible to photograph the corona without an eclipse. Every photographer knows that it is difficult to photograph a dull object in the presence of a bright one. By using coloured blue media, liquid, I believe, he cut off the blue rays and made a photograph which presented markings believed by some to be the corona. He was instrumental in sending Mr. Hay Woods to the Righi, in Switzerland, to pursue these experiments at a great elevation. He was there at the time we were having those curious pink sunsets. Those who were in the habit of observing such matters could see that peculiar glow, under favourable conditions, in the brightest sunlight. This gentleman's work in Switzerland was interfered with by the peculiar state of the atmosphere, but it was supposed his results corroborated those of Dr. Huggins. Another idea occurred to Dr. Huggins. He supposed that if during a total eclipse of the sun his results agreed, he should be able to show that the moon cuts off the rays of the corona when it comes up to the edge of the sun. The experiment was made during the last eclipse, and the results were not confirmatory of Dr. Huggins's ideas. I do not mean to say Dr. Huggins was not right, but at present the question is not settled. Pickering turned his attention to the subject of photographing the stars, and got four hundred and sixty-two stars on a plate 10×8 where fifty-eight were only shown on the chart by Dr. Gould, who showed stars of the ninth magnitude. To measure and plot fifty-eight stars is a work of very considerable labour, but it is only the labour of an hour or two if we use photography, so that the saving of time is enormous. In 1860 Dr. De la Rue went to Spain and succeeded in photographing a total eclipse of the sun, and proved the point as to the red prominences belonging to the sun. These red prominences are exceedingly brilliant masses of light which appear at certain places round the edge of the moon, very beautiful and generally of a rosy tint. They were a great mystery; nobody could tell what they were, and they could never be seen excepting during an eclipse, and the thing to prove was whether they really belonged to the sun. On photographs taken at the beginning of the eclipse the red prominences were seen on one side and at the end of the eclipse on the other side. As the moon progressed across the sun's disc the red prominences were covered up, thus demonstrating that they belonged to the sun. This proof is not needed now, the spectroscope reveals those objects without the assistance of an eclipse. About 1870 there was much speculation among astronomers as to the nature of the corona; some said it could only be an effect in our atmosphere produced by the light striking the edge of the moon, and had nothing to do with the sun. As photography settled the matter of the red prominences, it was naturally supposed that it might settle this. The Royal Astronomical Society, aided by the Royal Society and the Government, resolved to test the matter, and I had the pleasure of helping. I knew that all previous attempts to photograph eclipses had been made with the telescope, and how very difficult it was to take pictures with a telescope, the lenses in which were not corrected for the chemical rays. It occurred to me that the most sensible way was to photograph the eclipse as you would a landscape. I made inquiry to get the largest aperture lens I could; Mr. Dallmeyer had the only available instrument, and kindly lent it me, and with it I made some photographs. It was very lucky the whole thing was not a failure, as the clouds only just cleared away in time, leaving me only thirteen seconds of clear sky before the eclipse ended. The photograph taken at this time, when compared with others taken one thousand five hundred miles away, settled the point as to the corona being an appendage of the sun. The method I adopted in this instance has been used ever since in photographing

eclipses of the sun. I now come to speak of the work done in France by M. Janssen, at Mendon, and Messrs. P. and Prosper Henry, at the Paris Observatory. I may also say there are gentlemen at work in England pursuing the same line of work, and though I cannot show you very much of what they have done in stellar work, I can show some very beautiful photographs by Mr. Common. M. Janssen has given more attention to photographing the sun. I have here a photograph of the sun's surface, showing a very large spot visible to the naked eye in 1885. In this place, about twenty-five years ago, Mr. Nasmyth communicated a paper on the subject of the sun's surface, to which very little attention had been given before. Sir John Herschel and others had observed that the sun was not a smooth surface, but was broken up. Nasmyth said the surface appeared to be covered with objects like willow leaves. This called the attention of astronomers to the matter, especially the Rev. W. R. Dawes, who compared the appearance to a thatch of straw. Mr. Langley made a very beautiful drawing of a sunspot. Dr. Huggins made one totally different. But although they were all dissimilar I think all the observers mean the same thing, because one which is enlarged from the one I have passed round is so exactly like Dr. Huggins's drawing that one might almost say the same hand had drawn it, though one is a photograph and the other a drawing. It may be called the mosaic pattern. M. Janssen, in pursuing this subject, came to the conclusion that photography could do more than it had hitherto done. I will translate a few words from a paper he has sent me. M. Janssen says, "In a note presented to the Academy of France in December, 1877, . . . I said that photography offered not only, as is believed generally, the means of fixing luminous images, but that it constitutes a method of discovery in the sciences, and especially in astronomy. I added that the sensitive photographic plate, by reason of its admirable property of giving fixed images and rays much more extended than those which affect our retina—in fact, permitting the accumulation of radiations during a time more or less unlimited—that this sensitive film, I said, ought to be considered as the true retina of the scientist." Since the time this remarkable passage was written the Messrs. Henry have been busy photographing the stars. I will send round three photographs of parts of the constellation Cygnus, which contain stars down to the sixteenth magnitude, and to produce the negatives the exposure was from one hour and a quarter to three hours. You will notice that the stars at the corners are drawn out in the direction of the centre. That must be through a defect of the lens. I do not know that it diminishes the interest of these photographs, but if it should have the effect of lengthening the distances of the stars a great part of the plate could not be utilised. It requires one of the largest and most perfect instruments to show stars of the sixteenth magnitude. A star is really only an optical point, and has no disc. No stars, not even Sirius, have discs, but you see these have. The length of exposure must be the cause of it, as the more you expose the more the rays spread. Mr. Common used a reflecting telescope of about three feet aperture and thirty-six feet focal length, and of course he was working under very different circumstances.

Mr. Brothers then proceeded to the demonstration with the lantern, when he showed photographs illustrating the various matters referred to in his address. The point referred to in the passage quoted from M. Janssen's paper was illustrated by a photograph of the Pleiades, in which a nebula was discovered which had never been seen in any telescope. Mr. Brothers also thanked Messrs. Janssen, Henry, and Common, for their very beautiful photographs which had assisted so materially in illustrating the subject of the address.

Mr. J. S. POLLITT said in Norman Lockyer's work on solar physics the plan of blocking out the sun was recommended, and it stated that the red prominences were photographed by that method, not using a blue medium, but by a mask in front of the lens and taking the photograph in that way.

Mr. BROTHERS said the red prominences had never been photographed without an eclipse, but when the polariscope was used they could be seen.

A hearty vote of thanks was accorded to Mr. Brothers for his address.

Dr. C. P. BAHN exhibited some samples of Willesden paper, and explained its manufacture and its usefulness in various ways to photographers.

Mr. J. B. ROBINSON said he had made a developing dish of the paper, but it had spoiled his pictures.

Mr. Edwards exhibited a roller slide constructed by himself, and Mr. H. M. Whitefield a camera of novel construction which he had personally constructed, and which was considered by the members a clever piece of work for an amateur.

At the conclusion of the meeting there was an exhibition of small cameras and tripods, &c., from various makers, including Watson & Sons, Marlon, W. Watts, S. D. McKellen, J. Billeliff, J. A. Furnival, Hopkins Brothers, Chapman & Thornton, besides other exhibits in apparatus from Clibbey & Preston, Morgan & Kibb's roller slides, &c.

After the Hon. Secretary had introduced all the exhibits which had been sent from a distance, and whose representatives were not present, the formal meeting was adjourned, and the members walked round inspecting the numerous things of interest, and it was a late hour before the room was clear, after a most interesting and enjoyable evening.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

THE annual meeting of the above Society for election of officers and exhibition of lantern slides by members was held in the Old Town Hall on Wednesday, the 12th instant. There was an excellent attendance of members and ladies.

The minutes of last meeting were read and confirmed and one member proposed.

The election of officers was then proceeded with, and resulted in the following:—*President*: Mr. George Bankart.—*Vice-President*: Mr. C. Underwood.—*Treasurer*: Mr. W. Southrop.—*Committee*: Messrs. Toller, Southrop, Tucker and Broadhead.—*Hon. Secretary*: Mr. H. Pickering, High Cross-street.

The accounts were then presented, and, having been previously audited by Messrs. T. S. Taylor and W. Broadhead, and found correct, they were passed, and the Committee have pleasure in reporting a balance of nearly £5 in hand at the close of the first year of the Society's existence.

The lantern exhibition then commenced, Messrs. T. S. & W. Taylor, Manufacturing Opticians of this town and members of the Society, working their

biennial limelight lantern on an eighteen-foot screen, which was admirably managed and gave brilliant pictures, and brought out the slides in a very efficient manner.

Where all are good it is invidious to particularise, but the slides of Messrs. Tucker and Weatherhead were excellent and left nothing to be desired; there were slides exhibited also by Messrs. Broadhead, Taylor, Underwood, Alsop, &c., illustrating the various modes of development and exposure. The best slides of the evening were those reduced from whole-plate to lantern size.

After a hearty vote of thanks to Messrs. Taylor for their kindness in working the lantern, the company dispersed, after a most enjoyable evening.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

The annual meeting was held in the College of Physical Science, Newcastle, on Thursday, the 13th instant, at half-past seven p.m.—Mr. J. Downey in the chair.

After the usual routine business, Mr. Hinton Shand was elected a member. The voting papers for President and Council for 1887 were examined by scrutineers and the result announced as follows:—*President*: Professor A. S. Herschel, M.A., F.R.S., &c.—*Vice-Presidents*: Mr. J. P. Gibson, Hexham, and Mr. J. Downey, South Shields.—*Hon. Treasurer*: Mr. P. M. Laws.—*Hon. Secretary*: Mr. J. Pike.—*Committee*: Messrs. Anty, Galloway, E. Sawyer, Loyd Sawyer, Procter, Robson, Sinclair, Templeton, and Schumann.

The SECRETARY read the sixth annual report, and the TREASURER made his statement of receipts and expenditure for 1886; these were passed.

Mr. J. P. Gibson proposed a vote of thanks to the President and officers for their labours during the past year. This was put to the meeting and carried with acclamation.

A discussion followed on orthochromatic photography, in which Messrs. Gibson, Galloway, Downey, the Secretary, and others took part.

Two questions found in the question box were considered and the meeting adjourned.

SIXTH ANNUAL REPORT.

Gentlemen,—In accordance with our rules, I beg to hand you the Sixth Annual Report.

Early in the year it was unanimously decided to hold an exhibition of photographs, open to all amateur and professional photographers, at the Art Gallery. It having come to the knowledge of your Council that a Royal International Exhibition had been resolved upon for the Jubilee Year 1887, at which exhibition a special photographic section would be a feature, your Council considered the matter further, and came to the conclusion that it would be better to postpone our exhibition and join the Jubilee Executive in their endeavour to get together a good collection of photographs. In furtherance of this object, our Society provides for open competition gold, silver, and bronze medals. The editor of the *Amateur Photographer* also contributes a medal for amateur photographers, and I am glad to state that there is every prospect of a highly interesting and successful exhibition.

Papers have been read this year and demonstrations given by Mr. Cosens Way, the Rev. T. F. Hardwich, Professor Herschel (twice), and Mr. Pike; Mr. Jackson and Mr. Macleod gave at the January meeting a demonstration of lantern slides. A Sciopticon lantern has been presented to the Society by Mr. Maling. Contributions of books also by the President and the Rev. T. F. Hardwich, M.A. The thanks of the Association are due to the above-named gentlemen, also to the editors of the *Photographic News*, *THE BRITISH JOURNAL OF PHOTOGRAPHY*, *Amateur Photographer*, *Anthony's Bulletin*, *Photographic Journal*, and *Photographic World*, for journals and papers.

We have enrolled nine new members this year; on the other hand, we have lost two by death and seven by resignation.

Outdoor meetings were held at Jesmond Dene, North Shields, Rothbury, and Staward Peel. They were not well attended, the weather being very unsuitable for photographic purposes.

The expenses in connection with the exhibition are expected to be heavy, and although the Society expects to be reimbursed somewhat by the receipt of entrance fees, and can show, as will be seen, a very fair balance, it may be necessary to make a special effort to meet the extra expenditure. Several members have already contributed to a fund for the purchase of a "die" from which medals could be struck for this and any other exhibition it may be desirable to hold, but further contributions should be forthcoming before anything can be done in this direction.

In conclusion, it is desirable that all members should endeavour to take part in the Society's ordinary meetings by contributions of papers and discussion of various matters of interest. The question box is provided for the purpose of eliciting answers to questions sent by any member who may not be disposed to raise his question in open meeting. Members are also at liberty to bring a friend to the meetings.

Trusting to receive in due course promises of papers, &c., for the Society's meetings,

I remain, Gentlemen, yours faithfully,

J. PIKE, Hon. Secretary.

General Statement of Receipts and Expenditure for 1886.

P. M. LAWS, Hon. Treasurer.

Examined by E. SCHUMANN.

SUTTON SCIENTIFIC SOCIETY.

THE Photographic Sub-Committee of the above Society gave a most successful soirée on Thursday, the 20th instant, at the Public Hall, Sutton.

About four hundred and fifty visitors attended and seemed to greatly appreciate the efforts which were made to amuse and interest them. In the intervals

between the showing of slides in the optical lantern there was music in the shape of glees, solos, and instrumental pieces. The Geological Sub-Committee also kindly arranged a small geological exhibit, which had many visitors.

Turning to the photographic exhibition itself, it may be said that the Sub-Committee succeeded in bringing together a most interesting and even important display. The members themselves almost filled one side of the hall with frames of their own works, amongst them being excellent local and other views by Messrs. Ackland, Cathcart, Chivers, J. and F. Curtis, Foster, Goode, Jacques, Perrott, Wilkins, Wormald, and Mrs. Culverhouse. The most interesting of the frames contributed by friends included many splendid pictures; some views of Japan and others of Niagara Falls, lent respectively by Dr. Dresser and Mr. Walker, may be mentioned. The London dealers and manufacturers were also well to the fore.

The soirée broke up about half-past ten, and the Executive Committee—Messrs. Good, McCance, Cathcart, Chivers, and Perrott—may be congratulated on having organized a very successful evening's entertainment.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE third meeting of the current session was held in 20, George-street, on January 5, at eight o'clock.—The President occupied the chair.

Thirteen members were admitted.

Mr. H. BRENNER read a paper on *Beauty of Pose, Proportion, and Feature in Portraiture* [see page 53]. He illustrated his remarks and added to their interest by outlines and sketches on the blackboard.

Mr. S. Tamkin sent a short paper on *Photographic Society Table Talk*, which was read.

A roll holder sent for exhibition by Mr. J. M. Turnbull was explained. It was pointed out that in this holder no third roller is needed, the paper roll being contained in a receptacle from which it is paid out as required. The manner in which the exposures are marked off is an improvement over that of marginal prickers, which sometimes miss. Whenever the slide is drawn to expose, two perforators are released which puncture the centre of the paper at the limit of the exposure.

Mr. F. BRIGLIEN submitted a mechanical contrivance which might be styled an adaptor front for the camera. The object of it is to furnish a handy means of holding securely in position for any temporary purpose lenses of different sizes. Two sliding metal panels with V-shaped openings are made to approach and grip the lens, so that it is held at four points; and, in order to close the small openings left, a square piece of sheet rubber with a circular hole in it is fitted over the lens, and the whole kept tightly in position by elastic bands. The idea was favourably remarked upon.

A sample of a very translucent material termed "glacier" paper was handed round, kindly sent by the makers. It was examined in view of the possibility of utilising it as a support for gelatine emulsions. It is thicker than the tissues usually employed, and was affirmed to be impervious to watery solutions.

A number of ceramic enamel portraits of great beauty and softness, by Mr. J. G. Tunny, were exhibited and were much admired.

Messrs. Stürn & Co., Bremen, sent the illustrated prospectus of their new "secret" camera, for use under the vest, and described as "the newest invention upon the sphere of photography." This apparatus is declared by its German inventors to be extremely light and warranted capable of carrying ordinary dry plates. It is intended to be hung round the neck, the exposures being made through a buttonhole.

Mr. W. CROOKE remarked that the instrument was doubtless efficient enough, taking six pictures on one plate, but it was inconvenient that circular plates were required for it.

Correspondence.

23 Correspondents should never write on both sides of the paper.

PERMANENCE.

To the EDITORS.

GENTLEMEN,—I wish to call your attention to a fact which seems to be entirely overlooked in the controversy which is at present raging in your columns as to permanency in prints by various processes. The point which is neglected, and in which the essence of the dispute really lies, is the nature of permanency which is claimed for prints both by bromide and platinotype methods.

One gentleman, for instance, exposes prints by both processes to an atmosphere of sulphuretted hydrogen, or soaks them in some other chemical which would destroy almost anything which comes in contact with it; and then when the print becomes discoloured or fades altogether he flies to announce that this or that is not permanent.

This course of testing would be perfectly reasonable, I admit, if photographic albums consisting of baths of nitric acid or blotting-paper soaked in ammonium sulphide were in fashion; but it not being so, this is only begging the question.

The public do not wish to have prints which can withstand the united effects of the contents of a druggist's shop. We simply want them to be able to resist the effect of town air (say, London air, as I think that is the most impure) combined with damp. That is to say, that a print which will withstand for an indefinite period an exposure to oxygen, nitrogen, water, and an extremely diluted gaseous admixture of sulphuretted hydrogen and ammonia, has, in my opinion, at least a legitimate claim to be entitled permanent. This can only lead to one conclusion, and that is, that both gelatino-bromide pictures and

platinotype prints on paper, if properly executed, are to all intents and purposes permanent.

But platinotype has a decided advantage in this race for longevity, because this permanency is obtained with greater facility. A bromide print may very likely fade on account of insufficient washing, but with a picture in platinum this is not the case. A few rinses in acidulated water, and a wash for a minute or two under a tap, and you have a print that will, without the slightest doubt, withstand the test I have mentioned. But a bromide picture must be carefully fixed—"not too much" hypo, "but just enough"—and then as carefully washed until every trace of this hypo has been eliminated.

The result with the bromide process in nine cases out of ten is that the amateur finding his prints fade would blame the process and not his manipulation, and so platinum would get the credit for a superior permanency which it does not possess, both processes yielding results which are permanent in reality; but in one case these are obtained with but slight trouble, while the other needs a tedious and prolonged washing to insure this permanency.

Whatever may be said by the opponents of Mr. Willis's beautiful process, who are, I have noticed, in most cases interested parties, it is growing rapidly in favour day by day amongst both professionals and amateurs, which is a sure test of the quality of its results. That platinotype, like good wine, "needs no bush" being my opinion, I will conclude.—I am, yours, &c.,
VOX POPULI.

Peterborough, January 22, 1887.

To the Editors.

GENTLEMEN,—Were it not for the occasional scraps of useful information that crop up from time to time, discussion on this threadbare subject might long ago have been discontinued, perhaps with advantage. In your last issue Mr. H. B. Berkeley continues to dwell on the respective indestructibility of metallic platinum and silver, whose relative qualities have been well known ever since platinum was discovered. The real gist of the discussion is quite outside this, and I contend that the permanency of platinum, silver, or any other kind of print can scarcely be judged by comparison with anything else; each has a standard of its own. Mr. Berkeley has taken trouble to show that certain agencies will destroy silver prints and not platinum ones, which nobody does deny. If we know that certain preventable influences act prejudicially we avoid them. What would be thought of any one possessing a choice and valuable object if they always placed it in conditions to test its indestructibility? Usual people take care of such things, and if we know that by certain precautions we may prolong the existence of them for an indefinite period, we do so.

Now this applies to a good, properly prepared silver print, which I am perfectly convinced, if Mr. Berkeley is not, that such a print will, with proper care, last as long as shall fairly entitle it to be called permanent. My idea of non-permanency is, that the print shall in itself contain germs of destruction that will, no matter what care is taken, eventually cause the picture to commit suicide, so to say. If, however, a picture is only destroyed by outside influences from which careful storage will protect it, that picture is of itself undoubtedly permanent to all intents and purposes. Whether platinum or carbon are more so, has little bearing on the matter.—I am, yours, &c.,
EDWARD DUNMORE.

SULPHURATION OF PLATINUM AND OTHER PRINTS.

To the Editors.

GENTLEMEN,—I am much pleased to see the logical and discriminating way in which several writers have treated my little experiments on the sulphuration of prints, and in particular I thank Messrs. Beckett Lloyd and J. Martin for the light they have thrown on the matter. The quotation by the latter gentleman from the late Mr. William Shakespeare is most appropriate, and quite worthy of the subject. I quite agree with Mr. Martin (!).

One or two points have lately struck me as curious. First, everybody seems to think that I claim to have sounded the knell of platinotype. Nothing is further from my imagination. I think I have rather given it a lift. Before I published my experiments we had only assertions as our grounds of belief in the durability of platinum prints, now we know to what strong measures I had to resort before I could destroy the prints. Some people seem to assert I have not destroyed them yet, and they may be correct; I shall allude to that point shortly.

Another thing that strikes me as curious is that several people have written to me that they knew long ago that sulphuration would destroy platinotypes. Perhaps these gentlemen will come to the front now.

A few words on Mr. Lloyd's paper. He is quite right when he says that I wrote of the effect produced upon the prints as "yellowing," not as fading. In every case the colour was darkened, not "faded." But one little point has apparently been overlooked by everybody who has written. The blacks of the platinotypes appear unaltered because they are black. The effect may be there—I believe it is there—though we cannot easily detect it, because we cannot blacken or darken black. I think the blacks—that is the images—are affected. They are a different colour from what they were. This effect was more evident on the bromide prints; the dark parts of them were greatly changed, though they still

remained dark. In platinotypes the effect on the blacks is perhaps better seen after immersion in acid sulphide of potash. My great regret is that none of the gentlemen who write on this subject seem to have made experiments themselves, as I hoped and requested my readers would do. It is plain that this question must be settled before we go any further: Are the blacks really unaffected, or is it merely the case that we cannot detect any effect on the image? I pointed out the fact that while the back of the paper was apparently unaltered, the whites (at least) of the front are yellow. I admit at once that if the effect is produced only where there is no image, the image cannot be suspected; but the salts were at one time all over the front; how is it that now the front is affected and not the back? And I ask the question, for I am no chemist, is it quite certain, as some seem to assert and some to believe, (1), that the image is pure platinum alone? and, (2), that the white parts are ever entirely freed from the chemicals they undoubtedly at one time contained? Is it certain, is it indeed credible, that the whites have no kind or no amount whatever of passive action in the processes of printing and development? Granted that the light and chemical actions in the whites are very small and imperceptible, are we to take for granted that no action at all took place there? And if there is a reduction, however light, in the whites, we have again to ask the question, How is that the whites of the front yellowed while the back did not? Mr. Lloyd assumes, he says, "that the change in appearance of the platinum prints is confined to the paper," and he further takes it for granted "that the image itself remains wholly intact, since, from an experiment with bright platinum foil, H₂S seems to exercise no action on the metal." But I submit that we have no right to assume either that the change is confined to the paper, or that the image is pure platinum. I deny the first, and I ask proof of the second assumption. We have had enough of assumption in the matter.

Every philo-platinist surmises that the platinum prints I tested were not properly cleared of iron. I cannot answer "yea" or "nay" to this. I can neither deny nor own the "soft impeachment," I cannot of course state where I got the prints, but they were produced, as I said, one by an amateur of large experience in platinotype, the other by a gentleman who produces platinotypes commercially on a very large scale, as I understand. This, however, I will say: I myself soaked one of the same batch of prints (the commercial ones) in pretty strong HCl, and then washed it under a rose tap, and destroyed it utterly with acid KS. But I cannot swear that even my operations removed the iron. Considering the circumstances under which I produced the test bromide prints—they were utterly under exposed, and made long before I thought of testing them or anything else—the odds are about a hundred to one that neither the iron nor the hypo was entirely eliminated. But that has nothing to do with the matter; I am not now comparing bromide with platinotype, for I satisfied myself that so far as sulphur is concerned bromide prints have nothing to fear. My writing has, as some one says, done at least one good thing, it will be a warning to platinotypists to eliminate the iron. There is not the slightest doubt that if any iron remains in a print, and any sulphur has access to it, there will be mischief, just as surely as if any hypo is left in a print and sulphur gets at it. Mr. F. M. Edwards at the London and Provincial Photographic Association, a high authority on platinotype, said that when the HCl had fairly done its work it was "impossible for the prints to yellow under tests." He also produced prints and declared himself able, or believed himself able, to remove "any yellowness produced by chemical action on a platinum print." So the yellowness can be produced, but can, if produced, be removed. I regret I did not obtain one of the prints. I do not say I could stain it, but I should like to try my hand on a print above all suspicion of iron. If anybody will send me such a print I guarantee that I shall publish the results of my tests.

It is to me a real pleasure to discuss a matter with men who write and talk to the point, with such men as Mr. Lloyd, Mr. Martin, and Mr. Edwards. Even though we disagree, even though we fail to convince each other, there is a pleasure and a gain in ventilating the subject.

By private communication I have become aware of certain criticisms on my paper all proceeding from persons who evidently have not read my article carefully. A few words may be allowed to reply to them.

I do not deny, on the contrary, I assert, that platinotype is what we call a "permanent process." I do not deny, on the contrary, I asserted, that my test was practically severe, "out of all reason." My object mainly was to test bromide, not against platinotype but against albumen; this on account of an assertion made by a certain writer in these columns. Finding an action take place on the platinotypes I pushed my test further, in fact, beyond all reason. But in fairness I tested bromide as I did the other. Personally, I do not care a cent whether platinotype is durable or not.—I am, yours, &c.,
ANDREW PRINGLE.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—I really cannot allow some of the remarks made at the London and Provincial Photographic Association to pass without a word of protest.

Mr. B. J. Edwards says, "By gaslight a (Tailor's) orthochromatic plate is nearly twenty times more sensitive than an ordinary plate." Now I happen to have been testing different dry plates (about twenty-five

makes) with the best standard light ever proposed, and with Warnerke's sensitometer. I have used for years a No. 5 Bray's special gas-burner, burning, by Joslyn's indicator (Sugg), three feet exactly per hour. Although I have tested over one hundred plates of the same batch (Wratten's), I have never found my standard burner vary in the least.

Now, Tailfer's plate gives twenty-four on the sensitometer exposed to gas; three other makes of plates give the same, none of them orthochromatic; but one plate (Ilford), and one only, gives twenty-five, and so clearly that it would certainly give twenty-six if there were such a number. I should say that I have found that an exposure exactly five feet away from the above-mentioned burner, gives the same result as the sensitometer tablet with magnesium, but the former is far more reliable.—I am, yours, &c.,

F. P. LEON.

Woodlands, Clarence-road, Clapham Park, S.W., January 14, 1887.

THE PHOTOGRAPHIC EXHIBITION.

To the Editors.

GENTLEMEN,—I was pleased to see Mr. Pringle's letter in this week's JOURNAL, as I have been on the point of writing on the very subject he has taken up. Instead of getting better, things actually get worse each year. After much pressure being put upon me by the Secretary, I became a member of the Society, the advantages of course being pointed out which a country member living two hundred miles away would be supposed to have. At last I reluctantly consented to become a member, but I have not been able to discover the advantages, but certainly have found the great disadvantages. Since I became a member I have sent up to two Exhibitions twelve frames of photographs 15 x 12, each time along with a numbered list and a letter requesting that, however many were hung, they should be taken consecutively, as I had numbered them according to their merit as pictures. However, my instructions were entirely ignored, and the worst pictures were hung and the best put into limbo, and, to add insult to injury, the best of those that were hung were put at the back of a screen where nearly total darkness reigned. It was utterly impossible to see what any picture was like that was hung at the back of those screens. Whose idea it was to utilise the backs of those screens I don't know, but they could not have selected a better means to insult an exhibitor than by hanging his pictures on it; but I was a member, and of course it did not matter. The remainder of the selected pictures were skied and floored respectively.

I have put myself to considerable trouble and expense to please. The year before last I sent up for the pleasure of the visitors a large size stereoscope with the result related in a previous letter. The last Exhibition I sent a frame of 15 x 12 transparencies. I also sent between forty and fifty lantern slides for the Monday evening entertainments, with the result that some of the best were missing when returned, which was not till long after the Exhibition closed, and after repeated letters were written asking for their return, and when they did come there was not a word of explanation or reference to the missing ones, nor even a word of thanks in any shape or form; not much encouragement for any one to oblige by sending anything to the Society for exhibition.

I sincerely hope that something will be done before another Exhibition to remedy the defects of management. I don't know whether it is one of the privileges of country members to have a say in the election of officers, but I can say that I have had no opportunity of using that privilege, having never seen a voting paper.—I am, yours, &c.,

H. FOSYTH.

34, Bank-street, Bradford, January 22, 1887.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

To the Editors.

GENTLEMEN,—In your issue of the 14th instant appears a letter by "A Country Member," discussing the shortcomings of the Council of the Society, the temptation to answer which I successfully resisted at the time, but as in your last number Mr. Andrew Pringle, in a whirl of metaphor, exaggeration, insinuation, and oracular utterance, renew the assault, I shall be glad of a little of your space to examine and comment upon the statements made and the inferences therefrom. Let me only premise that anything I have to urge by way of defence, or explanation, is to be regarded as simply the individual opinion of one who happens to be both a member of the Photographic Society and of its Council.

In order of merit, as well as of style, allow me first to deal with the letter of "A Country Member." His communication, both in style and matter, is calm and reasonable; if severe on certain points, it is only from want of fuller information. He does not aim to be spiteful, nor is he careless in allegation, but writes, I do not doubt, from his point of view, in the interest of the general body of members. He is willing to admit that the Annual Exhibition, at least, is managed with skill and intelligence enough to be of service to the members and of interest to the public, and, in short, he writes without excited opinionativeness on matters that admit of argument, and in a manner that befits a gentleman. I feel he under-current of desire to be just so perceptible in "A Country Member's" remarks, that I am sure he would not have written "sharing with the retiring Vice-President the unenviable distinction of being absolutely at the bottom of the list" (of attendances) had he known that Colonel Stuart-Wortley has been disabled from assisting at the Council

Board throughout the session by a severe and painful accident. Further, had he known that our staunch friend, H. P. Robinson, underwent, at the close of 1885, a tremendous and most dangerous operation, that for days he hovered on the borders of "the Valley of the Shadow," that for weary months he was a great sufferer, and that his recovery is almost a miracle, he would have signalled the one attendance (travelling sixty-nine miles for that) as equal in interest and merit to any other person's seven. Here I fain would (and metaphorically do) shake hands with "A Country Member," and proceed to examine the arguments in his letter.

The first point is the question of attendances at the Council table, which your correspondent appears to think discreditable and a sign of danger and decay. He surely can have had little practical acquaintance with committees, or he would have seen at a glance that at the eight meetings of the season there were ninety-one attendances; that is to say, the President faced, on each occasion, an average of more than ten Councilmen, and if eleven elected representatives are not considered by him a sufficient number to confer on and determine the affairs of the Society, I think he only needs experience to correct his impressions. In the constitution of the Society, five members of the Council and the Chairman constitutes a quorum. Does "A Country Member" know of any society that expects to get all its committee together on ordinary occasions? Is he not aware that the legal quorum is always much below the total number of members, so as to allow for the contingencies of life and time, and secure a working average? Is he averse to the honorary election of a few members, who, having distinguished themselves in the science or the art of photography, confer some lustre on a council by joining it? Such men do not, as a rule, attend ordinary meetings, but yet represent reserved efficiency. For example, J. M. Swan, certainly a luminous name in the history of photography, was a member of Council, 1883-4-5. His attendances were few, but it was perfectly understood that in any emergencies of the Society he would have answered to the summons, and given time, thought, and, if necessary, money to serve it. The venerable Francis Bedford affords a similar example. I feel confident that if "A Country Member" will try, he can conceive that a society may wisely elect to its council some of its best friends, and not demand attendance at every business meeting. If this be so, and the questions I have asked above have any pertinence, then he will plainly see that his impression from the list of attendances by no means warrants the inference drawn, that "it is impossible to have a stronger argument against the continuance of the obsolete and absurd rule under which members of Council are elected." Instead of the attendances having been weak, they have been regular and strong.

As to annual election of the whole Council, that is a fair subject of consideration, although my friend has advanced no facts or arguments in support of his own view; perhaps he will furnish these in another communication to the Editors? On the other side, may be pointed out the fact that the annual retirement of one-third only of a council maintains a continuity of management, conserves experience, and is a guarantee from rash and intemperate change. It is also found expedient, for out of the 450 members of the Photographic Society, of whom a large number reside far away from the Metropolis, there is but a limited area of selection. The Council absorbs twenty-three members. These twenty-three to be worthy of the position must have qualifications of practical art, or scientific knowledge, or business aptitude, connected with photography; they must have a recognised social position, be able to work harmoniously together, and possess the confidence, at least, of large sections of the members. Further than this, they must be willing to serve, to give thought and time to the duties required, to accept the responsibilities of finance and of the Exhibition, and finally, must possess some crowning virtue of patience, so that after having done their best to save the Society, they may receive with celestial calm the railing accusations of any member with a bee in his bonnet, be he fiery Scot, or disappointed exhibitor, or both. Let "A Country Member" sit down, erase the present Council, and make out a list of twenty-three other members of the Society who can be depended on to serve and answer these conditions, and let us see his list in next week's paper! The natural limitations under which any Society works are soon perceived; no council, especially if it takes charge of an exhibition, can please everybody; a wise council does not try to please anybody, but simply endeavours to fulfil the duties undertaken, to the best of its ability, quietly certain the issues will not shame them.

But "A Country Member" need only to read the constitution of the Society to find that it is essentially democratic; that all the power is in the hands of the members. Its laws were made by the members—not by the Council; the laws can be altered or abrogated; and when he writes of the Council's "self-assumed prerogative of absolute government," he writes a resonant phrase, but with sound only in it, not sense.

As a step towards more fully understanding each other, will "A Country Member" kindly state, with particulars of date and circumstance, those suggestions of much-needed reform which have been made to the Council and which as a body it has opposed? There is nothing definite with which to grapple in a vague statement of this kind. It may impress unthinking people with a sense of fatuous obstinacy indulged at headquarters, but it cannot facilitate any reforms that are to be desired.

As to the final charge, that the transactions of the parent Society are inferior in interest to some of its offspring; if true, it is a charge that rests on the whole body of the members; the Council provides oppor-

tunity, electrical batteries, optical lantern, and a handsome place of meeting; it provides for fortnightly gatherings of members interested in technical matters, and would gladly welcome more contributions from country members than it receives. There is, of course, a certain exigency in its demands as to originality—scores of questions that afford interest to minor meetings have already been discussed sufficiently in Pall Mall. In parting with “A Country Member” I am ready to wish, with him, much more success to the monthly meetings. This depends partly on the more or less of invention and discovery in photographic art and science that come with the years, and partly on such men as he determining to help as well as to criticise. Country members can send papers to the Hon. Secretary to be brought before the Society.

To turn to Mr. Pringle and comment on his letter is by no means a genial task, for, in my opinion, in his communication he overleaps the bounds of fair criticism, and indulges in imputations that are unwarranted and offensive. His usually clear intelligence becomes perturbed with passion when discussing the merits of the Photographic Society and the terrible misdeeds of its Council. We would cull a few gems from his letter to illustrate this statement. “The Photographic Society of Great Britain is an example to other Societies—of what to avoid.” “Its blood is frozen, grievous wounds have broken out in its every part.” “Its meetings are stagnation.” “Chaos has reigned in the hanging department, Stygian darkness has enveloped the juries.” The officers are “wire-pullers.” “The Society tells off irresponsible men to deal judgment among the pictures.” He distinctly insinuates that the examination by the jury as a body, of the pictures set aside by the hangers as of least merit was a dishonest farce, and considers the hanging “to have been a perfect burlesque.” To all this screaming, spread-eagle, rhodomontade, the proper answer perchance is this: “Gentlemen, the members of the Photographic Society, behold on one side the accuser, bearing a shield emblazoned with the thistle, and this device—

‘I am Sir Oracle,
And when I ope my mouth
Let no dog bark.’

And on the other side behold the accused, Jurors of the Exhibition:

James Glaisher, F.R.S.	
Valentine Blanchard.	Francis Cobb, F.R.A.S.
P. H. Emerson, B.A., M.B.	J. Traill Taylor.
H. P. Robinson.	W. Wainwright, jun.

And deliver judgment as to which of the parties are ‘likely to be enveloped in Stygian darkness.’”

One may also consider the fact that the Press notices of the Exhibition were favourable as to its arrangement and the merit of its contents; that to it were sent a larger number of pictures than could possibly be hung; that the public attendance was larger than ever before, and that the awards have certainly given general content. In the very nature of things (including disappointed exhibitors) there must always be a certain amount of grumbling, both at the hanging and the awards; but Mr. Pringle takes evidence from excited fancy only, to show that the jurors did other than carry out, with intelligence and strict impartiality, the delicate duties of their office. “Oh, that mine enemy would write a book!” quoth the suffering Job. Had he lived in our times a letter or two to *THE BRITISH JOURNAL OF PHOTOGRAPHY* might have consoled him. It is impossible to accept without reserve Mr. Pringle’s valuation of his own opinions.

The points of his letter that have practical interest are two. First, to know if the permanent interest of the Society requires the Exhibition to be so managed that members have paramount claims on the space; and, secondly (a question of detail), Has the Hanging Committee conceded to the exhibitors of commercial houses interested in photography an unreasonable amount of space? To take the last question first, one may certainly answer it in the affirmative, if the excluded pictures could have filled the extra space with subjects of equal interest in art, quality, and in novelty. Further, if Mr. Pringle’s contention recommends itself to the Society that pictures hung too low or too high are insulted and disgraced, and would be far better in the cellar, then it is clear that very severe restrictions on the space will be imperative. A definite limit to each exhibitor must be prescribed, and to hang only on what may be called good lines would reduce the total of frames hung this year to one-half. This drastic change would indeed result in wholesale rejections, and wailing and gnashing of teeth. I know that last year the Council had under consideration the expediency of limiting the space for individual exhibitors, and arranging a special tariff for commercial firms whose specialities might be deemed worthy of more extended space than would be open to individual members. The time was not considered ripe for settlement, since, not so long ago, the question was, How shall the space at command be all utilised?—not to puzzle over nearly 200 pictures for which room could not be found; now, however, the question has become ripe and presses for solution. At the same time, this other fact must be borne in mind—the popularisation of the camera through the gelatino-bromide process is so great that pictures by the score are sent in for judgment that possess no claim (out of the minds of the producers) to be hung at our Exhibition, and rejections must be numerous if the standard of excellence is to be maintained. Further, be it remembered, the Council is bound to consider the outside public in its conduct of the Exhibition. The members of the Society do not pay one

penny at present towards the Exhibition, nor ever will while it is successful; on the contrary, they have free space, free catalogue, and free admission for themselves and for their friends. The outlay on the Exhibition may be roughly rated as amounting to two hundred and fifty pounds, and it is to the public the Society looks for reimbursement of this sum. Consequently the responsible managers are right in considering this element, and probably the pictures of vast proportions that can bear ten feet elevation, and give variety and distinction to the gallery, have exemplified the progress of the art and the improvements in processes, with educational effect and with satisfaction to the visitors.

As far as my connection with the Council of the Society, considered in relation to personal interests in autotype, is concerned, I may be permitted to state that I have conscientiously endeavoured to be, if possible, more than neutral—that is to say, that while submitting abundant examples of permanent photographic achievement to the jury, I have done so to give choice, and have more than once intimated, as clearly as the delicacy of the subject permitted, that rejections would not hurt my feelings. I desired the interest of the Exhibition to be alone considered. That autotype is entitled to recognition, and has been of service, need not be argued; and if it be thought the Hanging Committee has committed any error of judgment, it is not of a character to justify Mr. Pringle’s characteristic emphasis of inquiry, “Surely this is an outrage!”

To conclude my trespass on your courtesy, Gentlemen, there is now only to consider if members have a right to space (unless the work sent be flagrantly bad), if members’ frames should be only second to non-members’ frames, if the work of members, to a certain limit, should just be hung as well as possible; and if members are not to have these paramount advantages, will they be foolish enough to remain members?

The above statement of the question clearly shows Mr. Pringle’s opinion to be that the Photographic Society should not throw the Exhibition open to all comers, but practically should dare to conduct in London an exhibition only to exalt the work of its own members. It is perfectly certain that outsiders would cease to contribute if their productions are to be relegated to the space where he himself says pictures are either insulted or disgraced, and such an attempt would earn the contempt of the public and speedily involve the Society in financial troubles.

In my humble opinion the only worthy course is to invite unreservedly home and foreign competition; the best and most representative work of each year to be chosen on its merits alone, until at least two-thirds of the available space has been allotted. By that time (the manifestly poor subjects having been set aside) a fresh survey could be made, when this condition would be just, namely, when any two pictures competing for the same space, their merits being considered equal, one the work of a member, the other not so, the member’s claim should prevail. But the moment a jury ceases to prefer merit, the office is degraded, the exhibition injured, the progress of the art impeded, and the Society started on its decline.

The country members have always been faithful supporters of the Society, and as geographical conditions hinder their full participation in the general and technical meetings, they do not therefore complain. They probably feel that the parent Society has done, and is doing, good work; that its Council derives power only from the will of the members; that their interests are not neglected; and that some of Mr. Pringle’s written spasms are but “sound and fury, signifying nothing.”

W. S. BIRD.

THE AMATEUR QUESTION.

To the Editors.

GENTLEMEN,—Mr. J. H. T. Ellerbeck in your last issue, in order to get at the rank and file of the Liverpool Amateur Photographic Association, lays a statement of essentially private matters before the public at large.

It seems a necessity to reply, although the Council of our Association has studiously avoided bringing the matter before the public, feeling convinced that it was quite unnecessary to advertise the fact that Mr. Ellerbeck had taken up a line of action that made it a question whether the Council should resign and leave Mr. Ellerbeck in possession, or whether they should put the rules of the Association in force, and offer him the position of honorary member.

In order that the matter might be settled with the least possible detriment to Mr. Ellerbeck, I, as Secretary, published no report of our last two meetings, thinking that Mr. Ellerbeck’s long connection with our Association and his large personal services entitled him to our utmost forbearance. Your issue of the 17th December contained a report of our special meeting, evidently inserted for the purpose of exciting public sympathy in this matter, a report which was unofficial, and in the opinion of many members of the Council most unfair.

The laws of our Association stipulate that its affairs shall be governed by a Council, consisting of actually nineteen members. As a matter of course the majority of the Council present at any meeting decides what is to be done, and as to the members of the Association, I am inclined to think they will be abundantly satisfied that the action of their Council is for the best interests of the members.

Mr. Ellerbeck is quite correct in saying that three years since he sent in his resignation. He did so and it was refused, as up to that time we only knew him as an amateur. He states that there was an understanding that he was to confine himself to landscape work. I do not

remember that there was any understanding, but I believe we all expected that he would remain amongst us as an amateur amongst amateurs and not turn suddenly into a professional against his old friends.

Mr. Ellerbeck in a sentence which defies analysis, states that he got no notice of—something or other, and that at a Council meeting which deliberated for two hours and a half, he was practically excluded from the Association. He not only got the notice from me which every other member got, but I wrote him specially twice begging him to be present. He could get no notice of anything besides. The two and a half hours kindly discussion, in which he might have shared and in which he was not the only topic, ended in our proposing to make him an honorary member in consideration of his long and valuable services.

No charges have been brought against Mr. Ellerbeck; your columns are proof of that. Mr. Ellerbeck, in a very well planned footnote, draws in the Birkenhead Society, but forgets to state that he assisted in the warmest manner in the formation of that Society, and that its admirably conceived rules owe some of their efficiency to his presence on the evening when they were formulated, and that his presence was a source of pleasure to every member until one memorable meeting when the same course of action on his part which has led to his separation from the Liverpool Association, led to the discontinuance of his attendance at the Birkenhead Society.

In conclusion, I beg to traverse most emphatically Mr. Ellerbeck's closing sentence. Our roll of members is larger than before, our meetings have been the cause of the expression of much pleasure on the part of numerous members during the past year, and if all the subscriptions had been handed in, our *satisfactory* balance would have been even more satisfactory. Mr. Ellerbeck has looked after the finances with the utmost ability to the close of the annual meeting, and as he has had the matter in his own hands until nearly a week after the date of his letter to you, the interests of the Association cannot possibly have suffered.—I am, yours, &c.,

H. NORWOOD ATKINS, *late Hon. Secretary.*

Rock Ferry, January 21, 1887.

THE MENACES OF AMATEURISM.

To the Editors.

GENTLEMEN,—I read and reread Mr. Robertson's letter with mournful interest. I can see amateurism, when outside well-to-do people, will become a menace to the established professional. I read the letter thus, that in Glasgow clerks—and we all know that clerks marry and dwindle on wretched stipends—become amateurs, get hold of the thing, build glass-houses, give up their clerkships, become third-rate professionals, tout for custom, run down prices, and damage if not ruin men who have incurred large expense in conducting business on established lines. One can fancy this sort of thing going on until a street has more studios than grog shops. Apparatus cheap and nasty is answerable for some of this. I see no remedy. I only feel what I would do if a professional in such a case. I would have the best lens I could buy—would introduce larger direct heads, would trust more to artistic feeling and less to my retoucher, would try my best to educate a *clientèle* into liking my special work and especially platino heads. I would, in fact, try and get into a zone which the clerk and his cheap set must leave in my possession.—I am, yours, &c.,

WILLIAM ADCOCK.

Melton Mowbray, January, 1887.

THE AMATEUR PHOTOGRAPHIC ASSOCIATION.

To the Editors.

GENTLEMEN,—I think most of your readers will agree with me that the subjoined letter is a most unwarrantable act on the part of the Council of the Amateur Photographic Association, and that things have come to a pretty pass when a member of a Club or an Association cannot express "dissatisfaction" with the management without being kicked out.

It was early in 1885 when I first expressed "dissatisfaction," but it was not until the beginning of 1886 that the matter was brought to the notice of the Council. On June 4th, 1886, I paid my subscription, due by the rules then in force on the 1st. On the 15th of the same month a circular was sent to me, stating that the date of payment of subscriptions had been altered from June 1st to January 1st; but it was not until January 20th, 1887, that the Council (?) found out they wanted to have nothing more to do with me. Of course I shall not let the matter rest here, and have written to the Hon. Secretary to say that I insist on my allotment negatives being received, and shall claim all the privileges to which a member whose subscription has been paid and accepted is entitled to.—I am, yours, &c.,

S. P. TALBOT NICHOLS, *Lieut.-Colonel.*

St. Hilary, Cowbridge, South Wales, January 24, 1887.

The following is the letter referred to.

AMATEUR PHOTOGRAPHIC ASSOCIATION,
12, Old Bond-street, London, W.,
January 20, 1887.

DEAR SIR,—I am directed to return your negatives, as the Council did not expect to receive any further contributions from you after the great dissatisfaction expressed by you respecting the Society.

I am, dear Sir,

Yours very respectfully,

(Signed) ARTHUR J. MELHUSH, *Hon. Secretary.*

DEMISE OF THE SOUTH LONDON PHOTOGRAPHIC SOCIETY.

To the Editors.

GENTLEMEN,—I am surprised! You would hardly think it possible after being hon. secretary of a photographic society for many years; but the fact remains—I am surprised. Yes, and at Mr. George Smith, too—a friend, a gentleman, for whom I have great respect; one of your contributors who seldom writes what is not worth reading, and who rarely speaks but people listen; in fact, if they *didn't*, his modest, quiet voice would be lost in the smothered hum and murmur usually going on at our photographic meetings.

Mr. Smith asks, in your last impression, "Was the lantern evening of the South London Photographic Society, on the 6th instant, a success?" Why, the lantern meetings of the Society have always been a success. If Mr. Smith were a stranger, I could understand his query; but he has been a visiting member for some years, and has often shown excellent slides that have materially helped the success.

Of course I can understand Mr. Smith not liking his Woodbury slides frizzled up by the electric light. I can understand that as the pioneer of that useful little instrument, the "Scioticon," he prefers oil to anything else. I can understand familiarity with the small scale on which slides are shown at other societies having bred contempt for an eighteen-foot screen, and led him to regard a disc of reasonable size as a monstrosity, but it must be remembered that the late South London Society had advantages in this respect possessed by no other London society. If Mr. Smith prefers a benzoline lamp and a pocket-handkerchief, let him have them by all means, but he should not blame those who prefer (when they can get it) a sheet of ordinary and reasonable dimensions.

However, "Tis ill jesting with an aching heart." The South London Society (as such) has practically ceased to exist, and as many rumours are afloat about it, I shall be glad if you will kindly publish the following, a copy of which has been sent to each member:—

"LONDON, January 12th, 1887.

"At a Special Committee Meeting, held on the 23rd ult., it was decided: That as the probable number of members for 1887 would not provide sufficient income to defray the necessary expenses, an effort be made to amalgamate the Society with the Photographic Club, to which so many of the Society's members already belong.

"A deputation accordingly waited upon the Committee of the Photographic Club, and at a meeting of that body, January 5th, the following resolution was passed:—

"That the deputation from the South London Photographic Society be authorised to announce to their Committee that the Committee of the Photographic Club agree to accept the members of their Society as members of the Club, at the subscription not exceeding that of the South London Photographic Society, during and for the year 1887, and that the South London archives be deposited in the Club Library with a view to securing the continuity of the South London Society, which has for a long period been intimately connected with the history of the Club, and with which it has been considered a mutually desirable amalgamation."

"The Annual Lantern Meeting of the South London Society was, as you are aware, held on Thursday last; and thus, I regret to say, terminated the independent existence of what for twenty-seven years had been considered one of the principal photographic societies in the world."

"F. A. BRIDGE."

It may interest your readers to know that the scheme has met with the greatest approbation, and the desire to join the Photographic Club (by those not already members) has been almost unanimous.

Taking this opportunity of thanking the Editors of the journals for the courtesy shown to me officially in connection with the late Society, and also the many friends with whom it has brought me in contact for the ready help they have given me so willingly and so often,—I am, yours, &c.,

F. A. BRIDGE.

East Lodge, Dalston-lane, London.

THE WORK OF A PHOTOGRAPHIC SOCIETY.

To the Editors.

GENTLEMEN,—At the November meeting of the Newcastle Photographic Society I had occasion to complain of the difficulty I experienced in getting from members papers for discussion; I also stated that the Society had already covered to a great extent subjects of photographic interest. In sending a report of the meeting to the journals, I did not consider it necessary to give my own remarks *in extenso*; but as I find that the very short and condensed report has been made the subject of criticism in a paper by Mr. Forgan at a meeting of the Edinburgh Society, which I only noticed a week or so ago, I think some good may be done by an extended report in the form of a paper to the photographic journals of my remarks on that occasion.

I do not propose to criticise Mr. Forgan's remarks *seriatim*, when I say that our Association, since its institution in January, 1881, as will be seen from the published reports of its proceedings, has been favoured with papers on such subjects as *Lightning Photography*; *The Washing and Permanence of Silver Prints*; *Photo-micrography* (twice); *Carbon Printing*, with practical demonstrations (twice); *Dark-room Illumination*; *Platotype Printing*, with demonstrations (twice); *Transparency* (lantern) *Making* (twice); *The Oxhydrogen Limelight*, *Ethoxo Light*, &c., by the Rev. T. F. Hardwich (four times); *Demonstrations of Printing with Ferro-Prussiate*, and similar papers; *Photo-lithography*; *Photography in*

Natural Colours; Chemistry of Development; Enlarging; The Recovery of Residues; Landscape Photography for Amateurs; The Permanence of Prints; The History and Results of Improvements in Photographic Lenses; Artists versus Photographers; The Daguerreotype Process; Pinhole Photography; Retouching; The Advantages of Technical Education in Photography; Gray's Omega Paper, with demonstration; Art in Relation to Photography; Processes of Photography in Natural Colours, with demonstrations; Photo-spectrographic Analysis, &c.: add to this list incidental discussions on other matters, such as the *Photographing of Interiors; Orthochromatic Photography; Enlarging on Bromide Paper; Collodio-Bromide and Collodio-Chloride Work, &c.*; and I think my statement will be found fairly correct.

I gave a further list of subjects which would be suitable for discussion or papers, namely, The wet process, dry plate processes with the silver bath, gelatine and collodion emulsion processes, and the principles involved in each. The theory of development by the acid and alkaline methods. The theory of intensification. Printing in silver and other metals, toning and fixing. The collotype and powder processes. The calotype process. Woodburytype, stannotype, vitrified enamels. Special applications of photography to engraving; typography. Special applications of photography to astronomical and microscopical purposes, as well as for recording meteorological and other observations. I also referred to the questions given at the last examination in photography of the City and Guilds of London Institute, as affording further food for reflection and elaboration.

Our Society owns a small library, easily accessible to members, and I am quite certain that material for more than one paper or lecture is to be had from a perusal of any one of the volumes of the *JOURNAL* or *News* (alone) of the past twenty or so years.

I hope that the list of subjects given above may be useful to those of your readers who may be members of Photographic Associations; any additions thereto I, for one, should be thankful for.—I am, yours, &c.,
J. PIKE.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

H. HATTON, Dewsbury.—*Portrait of R. E. Lockwood.*
F. HOARE, Cirencester.—*Portrait of Colonel F. W. C. Master, The Ven. Archdeacon Hayward, and Lord Apsley.*
M. J. E. COLE, Keighley.—*Portrait of Rev. W. E. Goodman.*
J. CLARE & SON, Abergavenny.—*Portrait of J. Bishop and F. H. Williams.*
S. C. VOSPER.—*Drawing entitled "Dance of Death," Plymouth Guildhall.*

MORE LIGHT.—Try Newman, Soho-square.

QUADD.—Make a complaint to the General Post Office.

M. JACOLETTE.—Mr. Briginshaw's address is 21, Albert-road, Walthamstow.

F. D.—This is purely a business matter, and you will find a remedy in the County Court.

AMATEUR.—We quite share your sentiments, and if in your place would act in a similar manner.

G. A. W.—Tinfoil of a very thin kind used to be, and we believe is now, supplied by Messrs. Stanton Brothers, Shoe-lane.

J. BARKER SMITH.—Plates of extreme sensitiveness are supplied by all makers of repute.—We do not understand your query about condensers.

ESQUIRE.—Take with you all the chemicals necessary to keep you going for some time, and arrange with a respectable firm here to supply your orders from abroad.

E. S. P.—Dry the prints between blotting-paper, or else squeeze them down on a sheet of ebonite, and allow them to dry before taking them off. This will prevent them from curling.

C. S. HYARON.—We do not see how the proposed picture can be an infringement of your copyright, unless it be copied from your work; and you do not say that this is the case.

LANTERN.—The Woodbury process of making lantern slides is precisely the same as making prints on paper by the Woodbury process, except that in place of paper the impression is taken on glass.

S. A. Z.—If you read the article again you will see it is distinctly stated that the plates will not keep long after preparation. Why not experiment yourself, with a view to overcoming the difficulty, instead of asking us to do it?

R. BUGGA.—If the gas bag is in the condition you describe the best plan to adopt will be to throw it aside and purchase a new one. It is often a risky transaction to buy a second-hand gas bag, and it clearly was so in the present instance.

LOLO.—A saturated solution is the one usually employed; sometimes a small quantity of chloride of ammonium is added to increase its solubility. Bichloride of mercury is much more soluble in a solution of chloride of ammonium than it is in plain water.

C. A. S.—The spots appear to be caused by something either in the mounts or the mountant. If this be the case, unmounted prints produced at the same time should not show similar spots. If they do, then they must be due to something in the manipulation.

A. R. FENTON.—Kauri gum is chiefly used for making varnishes, though, so far as we are aware, not for photographic purposes. It is, we believe, being somewhat extensively employed in some oil varnishes as a substitute for copal and amber, but we are told it is not so good for the purpose as the two resins named.

A. McDUGALL writes: "I have recently been shown some photographs of lightning; are they genuine?"—They may be or they may not; without seeing them it is impossible to give our opinion. Genuine photographs have been taken of lightning, and we have seen several, but they all represent the discharge very differently to what it is depicted by painters.

J. H. WOLFF.—If you make the chloride of gold according to the instructions given in the article you can hardly fail, they are so clear and explicit. We cannot give the private addresses of our contributors. Each of the formulae are good. The one attested by the introducer's name is the latest he himself employs; the other is preferred by some, but, as we have said before, both are good.

F. G. P. complains that he recently sent several negatives to a firm to have enlargements made from them, but the results returned were very unsatisfactory, and he can neither obtain any redress nor his negatives back.—From a perusal of the letter, and assuming that the statements made are correct, we are of opinion that there will be no difficulty in obtaining redress through a court of law.

G. CONWAY inquires what is "eosine and erythrosine, which is being so much talked about just now in connection with orthochromatic photography."—In commerce there are several dozens of different eosines and many erythrosines. They are all colours obtained from the coal-tar products. The eosine supplied by the operative chemists is a tetrabromfluorescein, and the erythrosine a tetraiodfluorescein.

R. C. W. asks how furniture is to be photographed so as to show all the details of the ornamental work. He says that the polish in his case always obliterates them, though he has seen some pictures of pianos in which every detail, even to the grain of the wood, is perfect.—The best plan is to photograph the things before they are polished. This, no doubt, was the plan adopted in the case of the pictures referred to.

G. THOMPSON.—1. To know the coated side of a plate in semi-darkness, hold it in such a way that some light is reflected to the eye and, by comparing one side with another, the difference will soon be appreciated.—2. Considering the small cost of the sulphite, we advise you to throw away the old and obtain a fresh supply.—3. If the plate box be quite clean and free of smell from the wood, plates may be kept in them for a long time with out deterioration.

CORNISHMAN.—To make a solution of bitumen suitable for etching purp coarsely powder the bitumen and place it in a bottle, add benzole and we shake several times during the day; allow it to stand for two or three days and then decant the clear portion. This must afterwards be diluted to the strength required. As different samples of bitumen vary in solubility, no definite strength of solution can be given. It must be so dilute, however, that when it is dry on the plate it only forms a very attenuated film.

G. W. ATKINS.—Your example bears out what is mentioned in every manual, namely, that the first action of the bichloride of mercury is to darken and then to bleach the image. The bleaching action had commenced in the negative sent, and is plainly visible on the reverse side. The action being so slow in your case is owing to the solution being weak. We would advise you not to make any more copies of the subject you have experimented with, as it is illegal, notwithstanding that the size is so much less than the original.

W. T. F. M. INGALL writes to say he feels annoyed at finding anything published in the *ALMANAC* as his "last," this being in connection with the hydrokinone developer, because he has been making steps in advance in that direction. But if Mr. Ingall will turn once more to the *ALMANAC*, he will find that it is given as "the formula last published" by him, which there is no doubt it is. He says he has gone far beyond that. "I have now," he observes, "a single concentrated, colourless, developer which requires eight parts water to one part developer and, is good for glass and paper, especially Eastman's negative; but hydrokinone, which I still only use and believe in, has not attracted sufficient interest for me to write about it."

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, February 2, 1887, will be *The Photographic Uses of Artificial Light*.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday next a demonstration of the development of platinotype printing will be given by Mr. F. M. Edwards. Members who had prints given them for the purpose of staining are requested to bring them to the meeting or send them to the Secretary.

AMERICAN PHOTOGRAPHIC EXHIBITION.—The first annual exhibition of the combined work of the Photographic Society of Philadelphia, the Boston Camera Club, and the Society of Amateur Photographers of New York, including, also, exhibits from prominent American and European amateurs and professionals, will be held under the auspices of the Society of Amateur Photographers of New York, March 26 to April 2, 1887, at the Orgies' Gallery, 845, Broadway, New York. The exhibition will be inaugurated on Saturday evening, March 26, at eight p.m., by a private view, open to members and their friends. All pictures must be sent, charges prepaid, to the Society of Amateur Photographers of New York, 122, West Thirty-sixth-street, New York City, endorsed "For Annual Exhibition," and delivered before nine p.m., Saturday evening, March 19, 1887.

RECEIVED:—A. W. Beer; G. Mason; E. Drumore; J. H. Day; J. M. Turnbull; A. B.; G. R. Baker; and others.

* * * Through want of space we have been compelled to postpone "Editorial Table" and our "Department for Inexperienced Photographers;" also articles by G. W. Webster; A. Pumphrey; T. Stock; A. Pringle; R. Barnett; A. W. Scott.

PHOTOGRAPHY AND PHOSPHORESCENT SUBSTANCES.

THE connection between photography and phosphorescent substances has always been more or less intimate, though of late years and for practical purposes the application has been almost confined to sensitometer purposes. Still, some years back, many and various hopes were entertained that sulphide of calcium would have played a more important part than it has done, both for ornamental as well as utilitarian purposes. One of the earliest suggested applications of the then comparatively new preparation, made by the late W. B. Woodbury, was of an ornamental or sensational rather than a really useful nature, and consisted in making a print by the well-known "dusting on" process, using sulphide of calcium for the purpose, which should, after due exposure to light, be visible in the dark. The idea was a happy one, and as a curious experiment was successful enough; but for reasons that will be noticed later on it never made much headway.

A modification of the same idea was, we believe, the inception of Mr. Warnerke; at any rate, some eight years ago we witnessed an exhibition of his plan in the Hall of the Society of Arts. It consisted in exposing a phosphorescent tablet for a brief period under a transparency to magnesium light, when an aluminous replica of the picture was left upon the plate. This again was of little practical value. Very shortly after this, however, an attempt, or rather two separate attempts, were made to render sulphide of calcium available in a practically useful manner. Early in 1880 Mr. Leon Warnerke introduced his new actinometer, a description of which appeared in these pages at the time. In this instrument a tablet of phosphorescent material was utilised as the light absorbed, and the force of the impression was judged by means of a revolving disc with openings of greater or less translucency, each bearing a number which represented the force of the light. Later still the same gentleman introduced the sensitometer which bears his name, and which was adopted by the Sensitometer Committee appointed for the purpose, as the nearest approach to a "standard" that could be obtained. In this also, as is well known, the phosphorescent tablet is employed, its light passing through a graduated screen before it reaches the surface to be tested.

About the same period, namely, in 1880, hopes arose that sulphide of calcium might be utilised in an entirely different manner in connection with photography. Mr. Warnerke and Captain Darwin almost simultaneously communicated to the Photographic Society of Great Britain their respective methods, by which it was anticipated that a luminous image, produced either in the camera or by exposure under a negative, might be

used for the production of several copies by merely placing the impressed tablet in contact with successive sensitive plates. Mr. Warnerke's plan consisted in exposing the tablet in the camera for an extremely brief period, while Captain Darwin's experiments had been directed towards the reproduction of negatives. Both were successful so far as the mere reproduction of the image was concerned, but the impression so produced was quite useless in each case from want of sharpness. The lack of definition was attributed, in Mr. Warnerke's case, to the fact of the exposures being made through glass, and in Captain Darwin's to the unevenness of the phosphorescent surface, which, it was supposed, prevented perfect contact with both negative and sensitive plate. It was imagined that, given a perfectly smooth and even tablet, in which the phosphorescent was not covered by any appreciable thickness of glass or other transparent medium, images of perfect sharpness would be reproducible; but subsequent experiments proved the expectation to be futile, for reasons that will be explained.

Some time after Warnerke and Darwin's experiments had been published, a number of specimens of reproductions made in the manner referred to were exhibited at one of the meetings of the Photographic Club. These had been produced under the most favourable circumstances for securing sharpness, but still exhibited the vague and hazy appearance of their predecessors. In their production a luminous tablet was used, made by pouring a mixture of melted paraffine wax and sulphide of calcium on to a sheet of plate glass to a sufficient thickness to form a pretty solid slab. This, when cold, is easily detached from the glass, when of course it presents a perfectly plane and highly polished surface, such indeed as to secure the most intimate contact possible with any other plane surface. Still, as has been said, even under these circumstances sharpness was not secured, and the explanation is not far to seek. It is not in the slightest degree a question of want of contact but simply the *spreading* of the luminous image in the phosphorescent material itself—the luminous image is, in fact, incapable of sharpness, and consequently of transmitting sharpness.

This is readily seen by examining the outline of a sharp object, left after exposure to light, upon such a perfectly smooth tablet; though at a moderate distance it may appear clear and sharp, it is only on closer scrutiny that it is seen that the impression is vignettted from light into darkness, that the effect of light has spread in the substance of the material in much the same manner as ink or other liquid spreads in bibulous paper, or the impressed image on a sensitive film in the production of halation. The effect may be clearly shown by examining, side by side, the luminous images formed first by exposure through an aperture cut in opaque paper or card, and, again, that pre-

sented to the eye when the same opaque mask is pressed in close contact with the excited phosphorescent surface. The first will present the want of sharpness alluded to, while the other will be perfectly clear and well defined at whatever distance examined.

Some claim to novelty appears to have been put forward recently in America in connection with this subject, as we learn that Mr. F. E. Ives, of Philadelphia, has been producing images by means of the exposure of the phosphorescent tablet in the camera and subsequent contact with a sensitive plate. The importance of this method, if it were practically available, can scarcely be overrated, since it would render "instantaneous" photography in almost any light a possibility. The briefest exposure only is necessary to set up phosphorescence to some degree, and even though the luminosity may be invisible, or nearly so, to the eye, a prolonged contact with a sensitive photographic plate will produce a developable image. But, unfortunately, the question of definition intervenes, and shatters the whole fabric.

Still, we have read the brief account of Mr. Ives's experiments, given in our number of the 7th ultimo, with considerable interest, and have since repeated several similar ones made some years ago; and to those who have never witnessed these phenomena we cannot recommend a more instructive evening's amusement and employment, the materials for which are ready to hand.

But passing to another portion of Mr. Ives's researches and his deductions therefrom, it will be interesting to hear of the confirmation of his present views on the subject of the action of the red rays upon phosphorescent materials. It is a generally accepted and undoubted fact that the luminosity set up by exposure to white light or to the rays of higher refrangibility is rapidly destroyed by the subsequent action of those of the lower end of the spectrum. But Mr. Ives has noted that in a feebly excited plate the action of the red end of the spectrum is to cause a "temporary exaltation," followed by a "rapid exhaustion" of the luminosity, which he attributes to the effect of the heat rays. We can only say that so far we have been unable to obtain any such effect. Heat certainly will produce such an effect upon sulphide of calcium, which, if thrown upon a hot plate instantly glows, and then rapidly loses its luminosity, and if the temperature be very high, will probably have its phosphorescent power practically destroyed. This, however, we have always considered to be a purely chemical action, quite independent of any optical consideration, and certainly a far higher temperature is required to produce the effect than would be produced by submitting the phosphorescent substance to the action of the less refrangible rays of the spectrum, or of light passing through red glass.

In the absence of any details in connection with the manner in which Mr. Ives's experiments giving the results were conducted, we can see but one possible explanation of the phenomenon. We are speaking now from a sceptical point of view, though, of course, we may be wrong and Mr. Ives right. It seems possible that the exaltation spoken of may be the effect of diffused light from other portions of the spectrum. Thus, supposing the whole spectrum, or any considerable portion of it, to be allowed to fall on the screen, the action set up by the blue rays would entirely mask any slight exaltation arising from extraneous causes, though the latter might prove sufficiently powerful to produce an appreciable change on those portions of the spectrum where the exciting influence is absent.

This would account for the "temporary exaltation," while the more powerful extinguishing action of the red rays would then commence to bring about the "rapid exhaustion." We merely put this forward as a hypothetical explanation of a matter we cannot at present understand; but it is, of course, possible that Mr. Ives has exercised sufficient care to entirely isolate the different portions of the phosphorescent screen, and so prevent any diffusion of the different rays.

We shall look with interest for further particulars with regard to Mr. Ives's future experiments in this and similar directions; but with regard to his claim to be the first to "discover that photographs of dark objects can be made in the camera by the action of heat," &c., we must point out that he is years too late. Captain Abney, seven or eight years ago, is said to have produced, not a *photograph*, that is impossible, but an impression in the camera of a kettle of boiling water in absolute darkness, and amongst other lecture experiments has demonstrated to large audiences the possibility of forming an image by means of a lens with a sheet of ebonite—which transmits the heat rays—intervening between object and plate.

PAPER AND PELLICULAR NEGATIVES.

SINCE the introduction of the gelatino-bromide process, great advances have been made in paper and film negatives. However, some of the advantages gained by the substitution of paper or other flexible materials for glass, are not altogether unaccompanied by certain disadvantages. One is, that however translucent the paper may be rendered, there is a prejudice, whether well founded or not, that under some conditions its grain must, to an extent, show in the finished print. This objection of course does not apply if the negative be on a perfectly homogeneous film. One weak point in connection with paper and pellicular negatives alike, has more than once been alluded to at the meetings of the South London Photographic Society by, amongst others, Mr. E. Dunmore, namely, that unless the film be protected with a varnish of some kind, there will be considerable risk of its becoming stained in printing, as when unvarnished glass negatives are printed from.

With the view to overcoming the objection raised to the granularity of the paper, the Eastman Company, some time back, introduced what they termed stripping films. The negative, in this case, is taken, developed, fixed, and washed, as a paper one, and is then transferred from the paper to a thin sheet of transparent gelatine. In this way, although the negative is really taken on paper, it, when finished, is on a homogeneous pellicle of gelatine and is free from all trace of granularity. Recently, the same firm has introduced an improved method of transferring the film, which bids fair to become very popular, as it avoids a difficulty sometimes met with under the old system of working, while, at the same time, a protective coating is secured on either side of the negative.

As the advantages of the modified method of transferring, and the points wherein it differs from the old, may be the better understood, we shall describe the latter first, and point out its shortcomings. It may be well to briefly mention how the negative paper itself is prepared. The paper is first coated with a solution of plain gelatine. This is merely to serve as a substratum and takes no part in the formation of the picture. After this coating is dry the paper is pressed and then coated with the gelatine bromide emulsion, to which sufficient chrome alum has been added to render it, when dry, insoluble in hot water.

The old method of transferring the film is this: After the negative is developed, fixed, and washed, it is, while still wet, squeezed down upon a glass plate which has previously been coated with a thin solution of indiarubber and dried. The negative is then allowed to dry; and it is imperative that it becomes perfectly dry, otherwise the next operation—the stripping of the paper backing—will fail. When the whole is dry, the plate, with the adherent negative, is placed in hot water, which dissolves the soluble layer of gelatine next the paper and sets the latter free, leaving the insoluble gelatine bearing the image attached to the glass by the indiarubber. Next, a thin sheet of gelatine, which has been soaked in cold water until it is quite pliable, is squeezed on to the negative and allowed to dry. When dry the whole is stripped from the glass and any adhering indiarubber rubbed off with the finger. The negative is now finished.

By this method we obtain a film negative which is free from granularity, but it has no protection either back or front, and is therefore, open to the objection raised to paper or film negatives generally—and a varnish is not easy of application. Furthermore, in the development of the image, the pyrogallie acid exerts a tanning action upon the soluble gelatine substratum. Hence very hot water has to be used to effect the removal of the paper backing, and, in some instances, where the development has been prolonged, boiling water even has failed to dissolve the gelatine, and from this cause many negatives have been lost.

Here is the improved method of procedure by which this trouble is avoided and the time of the operation curtailed. A glass plate is rubbed over with French chalk, and then coated with plain collodion, such as that employed for enamelling prints, and immersed in water until all traces of the solvents are removed. The negative is now taken from the washing water, and squeezed on to the collodion. The plate is then placed between blotting-paper, under pressure, for a quarter of an hour or so. It is finally immersed in warm water, when the paper easily comes away, leaving the image firmly attached to the collodion. The reason why the paper can be so easily removed by the warm water, in this case, is that the insolubilising action of the pyro on the gelatine is next to *nil* until the latter has become dry. After the paper is removed a thin sheet of gelatine, softened in cold water, is squeezed on to the picture, and allowed to dry. Next, the gelatine is coated with collodion, and, when this is dry, the whole is stripped from the plate, the collodion applied to the glass forming part of the pellicular negative.

The advantage of this plan of transferring over the old is great. The first drying, which took many hours—sometimes a whole day—is dispensed with; added to this, the risk of the substratum becoming insoluble is avoided, this being a great gain. Furthermore, the finished negative is protected, both back and front, with a film of collodion.

If there are still any who look upon rain water as being "equal to distilled," their confidence would be shattered by the perusal of a very instructive table—published in the *Transactions of the Chemical Society*—giving detailed accounts of the examinations of rain water, conducted over a period of sixteen years at the Royal Agricultural College, Cirencester. From this table we find that the various samples of water, taken direct from the rain-gauge, showed the presence of chlorine to the extent of from two to twenty-six parts per million—a quantity which, calculated in connection with the amount of rainfall, would be equivalent to from 7 to 136 pounds of chloride of sodium per acre!

THE condition in which gold exists in the "alkaline toning bath" is a fruitful subject for speculation, for there are far many more theories propounded than facts collected to aid in forming a true opinion. The gold oxides have had less attention given to them than many other subjects of less importance to photographers, hence any addition to our knowledge is valuable. Recently Herr G. Kriess has been investigating the gold oxides, and his description of the properties of aurous oxide, Au_2O_3 , are very suggestive of that form assumed by gold in an acetate or other alkaline toning bath. He states that aurous oxide is dark violet when moist, greyish violet when dry; when freshly precipitated it dissolves in cold water, yielding an indigo coloured solution with a brownish fluorescence; it is insoluble in hot water. The solution has a characteristic absorption band when examined by the spectroscope. We do not remember to have observed any fluorescence in toning solutions, though this may be accounted for, possibly, by modifications caused by the presence of alkali. The most interesting point to discover would be whether the aurous oxide existed as such in the solution, or in combination with alkali as aurate, or finally, in both conditions.

WITH regard to the solubility of the double salts of gold—the form in which, practically, it is now only to be purchased from the photographic material dealers—an interesting account is given by Herr T. Rosenblatt. He finds the solubility is inversely proportional to the molecular weights of the salts. Taking as an example, he finds that, at a temperature of 16°C ., 58.2 parts are contained in 100 of solution, while at 60° there are 90 parts. The potassium salt at the lower temperature is only present in half the above proportion.

SHORTLY after the Eclipse Expedition of August, 1886, it was announced by Dr. Huggins that the results were unfavourable to his theory of photographing the corona of the sun in ordinary daylight, though others urged that it was premature to decide so soon upon the merits of the plan. Captain Darwin's preliminary account of his operations were recently communicated by Lord Rayleigh to the Royal Society, and with regard to this particular question he makes some reference to what has been termed by photographers "supplementary exposure." He says the instantaneous photographs of the corona, when developed, were complete blanks, proving that the exposure was too short. He points out, however, that this does not prove that the light of the corona was insufficient to cause an appreciable effect on the plate if combined with other light. "More light energy is necessary to start photographic action than is required to produce a visible difference of shade when once the action is started," he succinctly says upon this point.

WHILE stating that the results are adverse to the possibilities of obtaining photographs of the corona in sunlight, he considers it by no means proved that the method is impossible. "But at present I am inclined to consider that the result tends to show that a practical method of obtaining photographic records of the corona during sunlight is not likely to be obtained."

THE new glass of the Jena Glass Works, or rather, it should be termed, varieties of glasses, continue to hold the attention of scientific men interested in optical requirements, and Mr. Mayall, jun.'s, remarks at the last meeting of the Royal Microscopical Society met with great attention. It has already been stated that there is no difference between the chemical and visual foci of the new microscopic objectives, so that they can be used readily for photo-micrographic work; but then we must observe that also in the high powers of the ordinary construction this is usually the case: except in the lower powers it is frequently unnecessary to make any allowance.

MR. MAYALL further mentioned Dr. Schott's having expressed his conviction that several of the new kinds of glass will be found of great importance in the construction of photographic lenses. We are quite assured that our foremost English opticians are quite alive to any improvements that are to be found in the raw materials of their instruments—the optical glass; but it must be remembered that the high reputation enjoyed by our opticians

might be endangered if they too readily took up any new material without fully examining not only its optical, but its physical properties. Thus, to point to two instances only. There are some qualities of the new glasses that, owing to the action of the air upon them, can only be employed when cemented between two other pieces of glass. Then, again, when denser flints than had hitherto been made got introduced into the trade a number of years ago, it may be easily imagined the effects upon an optician's reputation if some of the samples on the market had been employed in photographic lens making, for their surfaces would not stand twelve months' action of the atmosphere.

AN idea thrown out by Mr. Glaisher in the course of his speech at the dinner on Monday evening is worthy of special attention. It is the desirableness of having premises either erected or purchased which will serve every purpose required by the Photographic Society of Great Britain, who now depend upon the Society of Artists in Water Colours. Having a large gallery of its own, the Society could then determine the best time for holding its exhibition without this being, as it now is, dependent upon the convenience of another body; it could have rooms in which to hold either small or large meetings; it would be free to employ the oxyhydrogen or any other light for projections, which it cannot now do; and, what is of great importance, under its roof might be gathered every Photographic Society and Club in London, who might be entitled to the use of rooms, hall, or laboratory, at a moderate stated rent.

WE would draw attention to one point referring to a matter that might be taken up by any photographer interested enough in the subject to give a little time to photographic astronomy. It is that in one second's exposure it is possible to get stars down to the sixth magnitude. It is, therefore, within the power of any photographer to produce star maps of any particular region by focussing his camera on the stars and giving one second's exposure. He might quite ignore the earth's motion, as it would not cause a blur that the eye could detect; indeed, assuming the one three-hundredth of an inch to be the limit of ordinary vision, such photographs, taken with a sixteen inch focus lens, would stand a small magnifying power, say, of two or three diameters, and still not appear blurred, while if the stars were allowed to travel so as to leave lines instead of points, stars of still lesser magnitude could be obtained in their maps.

ECHOES FROM THE SOCIETIES.

WHEN I made the remarks I did last week on the subject of the action of the red rays on the phosphorescent sulphide of calcium, I had not read the experiments of Mr. F. E. Ives, described at a meeting of the Franklin Institute. From these it would appear that those rays possess, first, an exciting effect upon a feebly luminous surface, which in turn is rapidly followed by total exhaustion of the luminosity. It is not stated how Mr. Ives's experiments were conducted, but I think the deduction he makes will be new to most of those who have had anything to do with phosphorescent substances.

Albumenised paper "dies hard." It has been threatened and threatened for many years, but seems to hold its own as firmly now, in company with numerous rivals, as it did when it practically filled the whole field. The London and Provincial Photographic Association had the matter under discussion recently, the behaviour of ready sensitised or "keeping" paper being chiefly in question. It was remarked incidentally by Mr. A. L. Henderson that there was nothing to equal newly sensitised paper, and with this statement I scarcely think any one will quarrel, though how few, except those who work on a large scale and constantly, now go to the trouble of floating their own paper. Even in many professional establishments the practice has been relinquished owing to the employment of the ready sensitised article enabling the proprietor to dispense with one, or perhaps two, extra hands, and in some cases to undertake his own printing. The question of comparative economy is, of course, his own, but it is due to his clients that the results he produces shall be the best attainable.

In the case of an amateur, the keeping paper is a boon inestimable.

How many of that class are able to seize the opportunity of a fine day to devote to printing? The sensitising and drying of even a small quantity of paper is a work of some time. What with getting out the necessaries, filtering the solution, floating, draining, and drying, consequently it has to be commenced early, and it is scarcely worth while to undertake it unless at least a considerable portion of the day can be devoted to printing. If the sensitising be performed overnight, it is ten chances to one that the luckless amateur finds the morning wet and dull, and totally unsuited for printing, and before he has a chance of using up his sensitised paper it has passed hopelessly into the sere and yellow. Indeed, in the hottest weather it is frequently impracticable to keep the paper for even so short a time as from overnight. Here the value of the commercial keeping paper is found. I say specially the *commercial*, for I have never yet met with a home-made article that at all approached it in quality. A spare half hour or hour before starting for business, or after returning on a summer evening, may be seized and utilised, and should the prints not be completed at the first attempt, no harm is done by putting the frames away until another opportunity arises. In such cases the question of a slight inferiority in quality may be waived in favour of the vastly greater convenience.

On the point of quality, however, it may be said that with some negatives the keeping paper will give actually better results, if it be in good condition, than newly sensitised. To wit, with these weak negatives a much more vigorous result is obtained, owing to the presence of the organic principle introduced, though conversely with a good negative of average density a softer and more harmonious result is obtained with freshly sensitised paper. Still, granting that one possible point in favour of the keeping article, there is no disputing the truth of Mr. Henderson's dictum, that the home-sensitised preparation is the better.

But the alleged superiority is chiefly in the direction of general behaviour, especially in facility of toning and economy of toning material, to say nothing of brilliancy and purity of the whites. On these grounds alone it is worth the while of any operator who can afford the time to sensitise his own paper, and in doing so he will find in the long run that the time devoted to sensitising will be economised in other ways, and his annual expenditure of gold materially reduced.

It was suggested at the same meeting that the cause of the difficulty frequently experienced in toning the keeping paper was probably due to the formation of a thin film of sulphide upon its surface. This may or may not be the case, but it appears to me more likely to arise from the gradual decomposition of the organic silver salt, usually citrate, contained in the albumen surface. The discolouration of freshly sensitised albumen paper is due to decomposition of the organic element, and this is also accompanied by difficulty of toning. With the keeping paper the tendency to yellowing of the albuminate of silver is held in check by the presence of free acid, but even without visible discolouration or with but the faintest metallic surface appearance the difficulty of toning will still supervene, and this result I attribute to the spontaneous decomposition of the unstable citrate of silver. It may be by sulphuration: but when properly stored, unless the sulphur be derived from the albumen itself it is not easy to see whence it comes. It is not difficult to conceive, however, how even *in vacuo* a gradual reduction of the silver salt may proceed, and few *quasi*-permanent substances are more prone to such change than the citrate and similar salts of silver.

By the way, before leaving the subject, I may say in reference to the paper alluded to by Mr. J. Traill Taylor as having been prepared by the late Mr. J. R. Johnson, probably twenty years ago, the existence of that paper in good and printable condition at the present day proves unmistakably the keeping power of citric acid. But Mr. Taylor confines himself to saying that it gives "a good print," he does not say whether that print was toned, and, if so, how it toned.

A particularly suggestive paper was read by Mr. H. H. O'Farrell before the Camera Club, on the subject of *Cameras and Field Apparatus*, the latter portion of the subject being however dismissed somewhat curtly. Mr. O'Farrell is very happy in the epigrammatic manner in which he expresses his idea of what a field camera should be. It should, he says, "be as light as is compatible with rigidity;

not as some makers seem inclined to read it, as rigid as is compatible with lightness." Would that "some makers" would take that to heart and act accordingly! I verily believe that no subject ever offered a wider opening for seathing sarcasm than the modern camera. Witness a joke I heard perpetrated a short time back. Amateur to friend who has just returned from two or three weeks' holiday, "Well, So-and-so, have you brought back many pictures?" "Only half a dozen or so." "How's that?" "Oh! it rained the first day." "Yes, but you had lots of fine weather afterwards." "Yes, but then I had no camera." Or again, look at the critic who, in discussing the good points of a particular camera, laid special stress upon the French polish which, he said, *kept it together*. This latter, I am assured, is a fact, and the statement, though probably exaggerated, undoubtedly points a moral.

I quite agree with Mr. O'Farrell when he says that both vertical and side swings are a necessity, whatever may be said to the contrary by manufacturers, whose particular patterns of instrument render it difficult, or impossible, to adapt one or the other. Again, with regard to the method of swinging from one extremity of the frame instead of from the centre, the almost universal plan nowadays, I wonder that photographers have not long ago insisted on its abolition. What can be more annoying than to have to spend several minutes altering and realtering focus and swing until at last the happy combination of positions is accidentally secured? When the swing takes place from the centre nothing is easier than to get the general focus in the middle of the plate, and then to alter the swing until the necessary straightening of the lines is secured or the requisite sharpness given to the foreground. With most forms of camera, the change could be made if insisted on. As things are at present, I know I frequently shun the use of the swing back, simply on account of the extra trouble it entails.

The lateral and vertical motion of the lens front is also a point that may be much improved in many of the modern cameras, and there is no earthly excuse for negligence in the matter. Any amount of traverse can be secured, almost from edge to edge of the plate, by the adoption of the principle I saw applied to a camera front in the last Exhibition, namely, the combination of a narrow solid wooden front and a bellows, or "gusset."

I do not quite follow his description of his proposed method of taking smaller pictures than the full size the camera is capable of, though undoubtedly Mr. O'Farrell is right in saying there is room for some such device. Many people would like to work two sizes in the field if it were not for the trouble and weight of two cameras. I cannot agree in his remarks either as to the reversible back adding unnecessarily to the weight and bulk of the camera, or that great extension of the body is unnecessary in field work. The first I consider one of the most valuable improvements made to the field camera in modern times, while if cameras and lenses of longer focus were more generally used it would not be to the detriment of much of the landscape work turned out.

On the whole, Mr. O'Farrell's paper is a suggestive one, and is a valuable addition to the literature of the subject which makers as well as users would do well to study.

MONITOR.

THREE PRINTING PROCESSES AND THE SULPHURING OF PLATINUM PRINTS.

For some little time I have held the opinion that the acrimonious discussion, the sort of "triangular duel," that has for a considerable period been filling valuable space in the columns of this JOURNAL was much to be deplored. I am, however, beginning to waver in this view, for it has enabled the very worst and the very best to be said by friends and opponents of the respective processes, thus giving the unbiassed an excellent opportunity of forming a calm judgment. Personally, I think I may claim to be quite without bias, being, as I am, on friendly relations with the representatives of each of the older processes, having worked in autotype when the practical workers might almost be counted on the fingers of one hand, and having printed in platinotype for many years. I have worked, and continue to work, the two processes side by side, finding them in no sense rivals, each possessing certain advantages over the other, and each capable of first-class results.

When the very highest class of work is to be done platinotype cannot be excelled. I have tried it both in portraiture and in landscape, for single pictures and for book illustrations, for plain and for coloured pictures. I look upon it as the process to be selected—if those colour or colours which only can be produced by it be considered suitable for the desired end—for the highest class of work. But it is not, in my opinion, to be selected for that class of work where negatives of but indifferent character are likely to be at all frequent.

Autotype also is capable of very beautiful results. It has not the perfect purity in the whites that the former can give, but it is far more elastic in its adaptabilities, and is such a first-rate all-round process that I am often surprised there are not a larger number of photographers practising it on their own premises than seems to be the case. Its difficulties are easily surmounted by the exercise of a little care and thought. Besides, what is any process worth to a photographer if it can be learnt in a lesson, and there is then no further experience to be gained? I am sorry that the method of double transfer from grained zinc seems to be almost a thing of the past, for the effect obtained by the matt surface was singularly refined, pleasing, and artistic.

With regard to the many emulsion processes upon paper, it would be premature in me to pass an opinion as to their artistic capabilities in everyday work, and I therefore confine myself to subjects that I have given much attention to, this method being too young for me to be able to say much as to its possibilities. That it has great power of artistic expression is shown by the results already before the public.

As to the reliability of the two processes I am familiar with, it appears to me that photographers have facts enough before them to enable them to form their own conclusions. In each we have a paper basis, but there the simile ends; for in one the image lies within the texture of the paper, and is, let us say, alleged, to be composed of metallic platinum; in the other it lies on the paper in a film of gelatine, and is composed of carbon in the main, with some trace of a chromium salt, and a quantity of pigment, supposedly an alizarine compound.

I may say I feel quite content to believe that the image in a platinotype picture is platinum, and as a chemist I believe that it—the image—would not be altered after the lapse of a hundred or two years. Similarly as to autotype, it is my strong belief that the carbon *per se* will not alter in that time, though the companion pigment might—the latter is an open question—and I also am quite content with the chances of the gelatine remaining unaltered for a few centuries; and although it certainly might leave the paper I consider such an occurrence unlikely. There then remains the paper. It is, by the way, rather amusing to see how novel a discovery it is by many considered that paper should become discoloured in the light, for the fact has been known to experts for years, and, indeed, a reference to any well-kept library tells the same story to any one who cares to inquire. The slight amount of chromium left in an autotype print is not likely to be of the slightest injury, and we have only to consider the possibilities with platinotype, which I will deal with fully on account of a recent article upon its results.

Mr. Pringle has done the process a good turn, and also photographers generally, by calling attention to the fact that the whites of a platinum print, done by an assumedly careful worker, may be yellowed by the application of sulphuretted hydrogen. I have seen the experimental slips he has earned the thanks of the profession by bringing forward, and some of them are a darker yellow than I should have thought likely. The image itself to all appearance is not altered. The effect is important enough to render it worth while to spend some time in ascertaining its cause, and with this object in view I have made a series of experiments which I proceed to detail.

The first point was to repeat Mr. Pringle's experiments, and this I did by tearing a number of slips from waste platinotype vignettes, where I should have a sufficient area of white surface for comparison. Preferring sulphide of ammonium solution to sulphuretted hydrogen, I immersed the slips in a strong solution of the former and left them exposed to its action for thirty-six hours. Result, a perceptible change of colour, not the same depth in each slip, and partaking more of a grey than a yellow tone. I cannot quite understand the cause

of the latter colour in some of Mr. Pringle's slips. I am not disinclined to imagine that he left them in the light and that partial decomposition of the gas had occurred with precipitation of sulphur. This, however, does not affect the deductions to be drawn.

The slips were all carefully dried and compared with the corresponding untouched halves, for thus only could the proper tone of the colouration be perceived. It was in no case so deep as to have seriously interfered with the value of a picture for hanging, but certainly it would be better away. Knowing the large quantity of iron that there is at one time upon the surface of the paper, it was not difficult to imagine that a trace of it was left. The possibility of this danger appears to have been foreseen by the Company who, in their latest instructions, give (I speak from memory) a further acid bath beyond what they first recommended. I accordingly proceeded to test the stain for iron. Boiling oxalic acid solution instantly removed most of the discolouration; but upon drying there was still a faint trace of grey, very possibly the last trace of platinum salt not washed out and reduced to metal.

The result was so suggestive of iron that I did not proceed further with this stage of the experiments, but at once set to work on the check slips. These, again, I tore up with my fingers (to avoid the possibility of introducing iron from the friction of the blades of the scissors), and digested for three or four hours at a temperature of 150° Fahr. in a strong, "pure" hydrochloric acid solution, and finished by boiling the whole for half an hour. To check the experiment I tested the acid itself for iron, as it was simply commercially "pure." It gave only a pale pink with sulphocyanide of potassium, and a scarcely perceptible alteration with ferrocyanide of potassium.

Applying these same tests to the acid in which the paper had been boiled the presence of iron was unmistakable, the sulphocyanide gave a deep rose when the acid was diluted with five times its bulk of water, and the ferrocyanide gave a good blue when an equal bulk of water had been added. Here was plain proof of the presence of iron in quantity, enough to cause all the observed discolouration by sulphur as seen in the prints submitted to the original test. How did it get there? Was it in the paper to start with, or was it only introduced in the preparation of the paper for printing in platinotype? It is quite possible that it may have been introduced in each stage, for it is at all times difficult to obtain paper entirely free from traces of iron, and it can easily be seen how the last trace of the purposely introduced iron salt might not be removed in the washing operations. It is possible also that the iron might form a compound with the organic matter in the paper, or perhaps the paper itself, and, as this might be looked upon as a substance somewhat analogous to a lake, it is quite possible that the substitution of oxalate of ammonia for the potash salt might be advantageous when one remembers the remarkable solvent powers of the former upon aluminous lakes.

As I have said, any observations upon emulsion prints would not be those of an old practitioner; but I may at the end of my remarks put the question as it presents itself to me. Here we have paper again as a basis, subject to the same influences as in the other two cases; a gelatine film, as in autotype, to contain the image—an image composed largely of reduced silver—and, finally, the possibility of the introduction of deleterious matter in the film. The latter is a difficulty not necessarily insurmountable, but one which photographers through unfortunate albumenised print experiences rather fight shy of. Then there is the silver image; and with regard to that there is first a question could the atmosphere obtain access to it through the gelatine that imprisons it? and next, could it do any harm if it arrived there? Here every one is able to form his own opinion, and it would be futile of me to direct it. I wish the heartiest success to the three rival processes; I hope that what I have written will tend to encourage the practice of each and all.

G. WATMOUGH WEBSTER, F.C.S.

ACCESSORIES OF THE LANTERN.

CHAPTER II.—GAS BAGS (*continued*).

Testing the Gases.—If a bag is suspected of containing a mixture of oxygen and coal gas, a light should on no account be applied to the open tap of the bag to ascertain if such is the case. Such a plan would no doubt be very effective, since, if the gas were to explode and burst the bag, it would be proof positive that there was such a

mixture. As we cannot afford to risk the bag in this way, we will adopt a safer method as follows:—A little of the suspected gas is squeezed out of the bag into an eight or twelve-ounce wide-mouthed vessel, such as an empty lime bottle. The bottle is easily filled with the gas by holding it over the open stopcock, so that the gas may blow for a few seconds into the bottle, which is then corked to prevent its aerial contents escaping by diffusion into the atmosphere. The bottle, having been removed from the vicinity of the bag, is uncorked and a lighted match is dropped in. If the match burns very brightly the bottle contains oxygen; if a lambent flame issues from the mouth for a few seconds it is due to coal gas; but if a "pop" or miniature explosion takes place the bag should be immediately taken into the open air and emptied of the gas it contains, which is an explosive compound of oxygen and coal gas.

This plan should also be adopted when a bag which is not suspected of containing a mixture of gases is tested to ascertain the nature of its contents. The usual way of doing this is to apply a light to the tap of the bag, which is partly opened so as to allow some of the gas to escape. This latter method is tolerably safe if the tap is held in a horizontal position and the gas is quite pure; but, as mistakes sometimes occur in the filling of bags, an explosion might result from this way of testing, hence the bottle method is to be preferred.

Capacity of Gas Bags.—The capacity of a bag is usually calculated by multiplying together the three dimensions—length, breadth, and depth; this result being halved gives the capacity of the bag as a wedge with flat sides. But as the sides do not remain flat, but bulge out considerably under pressure, the capacity is thereby increased—hence it is customary to add one-fourth to the wedge volume, in order to ascertain the amount of gas the bag will contain. Thus, assuming that a bag is three feet long, two feet wide, and one foot in height of wedge, we find its capacity as a wedge with flat sides to be three cubic feet, and adding the amount due to the bulging we get three and three-quarter cubic feet as the amount of gas that the bag will hold.

A bag containing four or five cubic feet is sufficient to supply a safety blow-through jet of 200 candle-power with gas during a two hours' exhibition. Larger bags are used for mixed gas jets, as these require a higher gas pressure. A jet with a moderate sized aperture in the nozzle burner, giving a light equal to 300 or 400 candles, will need bags holding six or seven cubic feet each; while the more powerful jets with large apertures, giving a light of from 500 to 700 candle-power, should have a pair of bags capable of containing each at least ten cubic feet of gas.

It is, of course, much better to have an excess of gas than too little of it; there should be a little surplus gas left after an exhibition, so as not to run the risk of being short in the case of a slight accidental leakage. This reserve may be regarded as the premium by which the success of the exhibition is insured.

Repairing Leaky Gas Bags.—When a bag is found to be leaky, it is well to decide what the cause is—it may be due to simple corrosion of the indiarubber by the gases or it may be caused by accident. In the case of general corrosion it will be scarcely worth while repairing the bag, as no real good would be effected unless the bag was completely recovered all over, which would cost nearly as much as a new bag. The leak may occur only in one place at first, and if a patch is put on, the bag may be used a little longer; but fresh leaks will occur so fast and will give so much trouble that it is poor economy to delay purchasing a new bag. A leak of corrosion is not confined to a small area, for the gas will slowly ooze out over, perhaps, a square foot of surface. It is often a difficult matter to find out the locality of such a leak, as the escaping gas diffuses so quickly into the atmosphere that the ordinary tests may fail to detect it; in such a case the only way is to put the bag, when full of gas, under a heavy pressure, so as to increase the quantity of gas issuing from the defective place.

Accidental leaks offer a far greater inducement to be repaired, as, if properly done, the bag is practically as good as new. Leaks of this class may occur in bags both new and old. They are caused by many things, such as the bursting of bags by over pressure while between the pressure boards, bursting by being overcharged with gas from the retort, giving way of a seam, rents produced in travelling, frayed portions which have been caused by dragging the bag over a rough surface, malicious pricks with knives, pins, and nails, and, in fact, every kind of damage affecting only a small part of the bag. I once had a gas bag run over by a railway train. Such an accident is not an everyday occurrence; it was caused by the upsetting of a porter's truck containing the lantern apparatus while crossing the rails about midnight, so as to reach the far platform of

the station at Wakefield. A train was advancing fast to the spot, and there was just time to jerk the lantern box and pressure boards out of the way—the rest had to take their chance; but the only damage done was to the gas bag, which had a piece a foot in diameter cut neatly out of it. This was an instance of an accidental leakage well worth repairing. A large patch was cemented on and the bag did as good service afterwards as though no such incident had occurred.

The testing and repairing of a gas bag is quite within the power of the average lanternist to accomplish; it is a simple matter, and it is by no means a necessity to send the bag to the maker or to an india-rubber shop to be doctored. Probably the first intimation that something is wrong with the bag will be the fact of the gas running short during some important exhibition, which causes the last few slides to follow one another with unwonted celerity, or else they are not shown at all. If the rubber pipes and the connections are found to be perfect, the fault must lie with the gas bag. This is easily ascertained by filling the bag with air or coal gas, and leaving it all night under pressure. If it is empty, or nearly so, in the morning, it is evident there is a leak somewhere, and our next business is to find out where it is.

If the bag has contained oxygen it should be thoroughly freed from that gas, first by rolling the bag up as tightly as possible to expel the gas, then by partly refilling the bag with air and again emptying, and, lastly, by filling it one-third full of coal gas and emptying afresh in the open air. It will then be safe to fill it as full as possible with coal gas and to apply the tests.

If the leakage is a large one it can easily be detected by the slight rushing sound and odour of the gas when under pressure, but if there is only a small leak, or perhaps several small leaks, this method fails. The test is then to carefully pass a small flame, such as that of a candle, all over the surface of the bag when under pressure; the leaks will be indicated by a small blue flame appearing where the gas escapes, which should of course be immediately extinguished with the aid of a damp cloth. The position of a leak when ascertained should be marked with chalk; it will often be found that the gas oozes out in more places than one—each of these should be also marked in turn.

I have mentioned a lighted candle as the test, but it is rather a dirty plan, as it drops grease on to the cloth; it is much better to attach one end of a long rubber tube to a gasfitting connected with the main and to put a brass pipe into the other end. Sufficient gas should be turned on to give a small blue flame an inch high at the orifice of this brass pipe, which can then be passed over the surface of the bag as handily as the candle. It is best to conduct this operation in a dull light, as a minute leak would yield so small a flame as to be invisible in bright daylight.

If the leaks are small it may be necessary to apply great pressure to render them evident. This may be accomplished by putting about a cubic foot of gas from the main into a second gas bag, the two bags are then connected by a rubber tube, and the second bag is rolled up into a small compass and a weight put on it, so as to force the extra foot of gas into the bag to be tested, which will become thereby drum tight; by thus filling a bag with as much gas as can be got into it, and subsequently applying pressure, even the tiniest leaks may be detected.

Having duly marked with chalk all defective places, the bag may then be emptied and the patches cemented on. The patches are cut out of india-rubber cloth, which should be "double sheet," consisting of a layer of rubber between two cloths. The thin single sheet mackintosh is not sufficiently durable. If black waterproof cannot be had the white will answer, as it can be darkened afterwards by being brushed over with a black pigment.

The patches should not be less than six inches square, and are best cut cushion shape. A tin of india-rubber solution being purchased, one side of the patch is smeared evenly over with the cement, and allowed a couple of hours to dry; the part of the gas bag where the patch is wanted is treated in the same way. A second thin coating of cement may then be applied to both, and also allowed to dry. The patch is then put on the bag, so that the two dry cemented surfaces come together; they will adhere very firmly, and after being well beaten with a wooden mallet, to ensure thorough contact, the leak will be permanently and completely stopped.

ALBERT WM. SCOTT.

METHODS OF RETOUCHING.

I.

I THINK it may fairly be considered a disputed point as to the proper order of acquiring a thorough knowledge of, and proficiency in, the art of retouching. Some hold to the idea that *method* is the primary necessity, others that a thorough knowledge of all the

minute requirements of a negative, and how they should be treated, should be the first anxiety of an intending retoucher. Personally, I am somewhat disposed to favour the latter opinion. I have always found that pupils, when once they acquire a certain proficiency in any *method* of working, cease to direct further attention to the study of the face. This has a very baneful effect in the end. The student falling into this habit may secure a very pretty and effective method, but the pictures he will turn out will be thoroughly devoid of that animation and expression so necessary to a true and life-like portrait. On the contrary, when he has given his attention fully to the study of the face, and thoroughly mastered all the effects of light and shade upon the muscles of same, he is in a safe position to start upon acquiring a method suitable to himself for the carrying out of the improvements that may be necessary on any negative which he may undertake to retouch.

As before laid down, it is impossible to know too much about the anatomy of the face, and I honestly advise every one desiring to become competent retouchers, to spare no pains in acquiring a thorough knowledge of it, before seeking for a method or style of working. By this means, too, there will be no hesitation while wavering between one style and another as to what you will do. You work ahead, and working suddenly realise that you have acquired a method of your own for carrying out the necessary treatment of a defective negative. Practice, then, will bring you not only proficiency but also rapidity of execution. I do not lay this down as a hard-and-fast rule, but if given a little consideration I feel confident it will have at least sufficient weight to balance what may be considered liberally a matter of opinion.

As may be gleaned from these remarks, I have no special method which I would put forward as the only and best one to be adopted by a beginner. One retoucher may have a very widely different style from another, and yet the results be so similar that one could scarcely say which was which. Of course, in such cases the two retouchers must have the same sentiments regarding the treatment of the muscles of the face; if they have not (even if their style be *identical* instead of broadly *different*), the most uneducated observer can discern the difference. This again proves the importance of the knowledge of the anatomy of the face, if such were still wanting. It is this same knowledge which marks the difference between the really competent and artistic retoucher and his less instructed comrade.

The first and most necessary implement used in retouching a negative, as all no doubt know, is the pencil. The method of using same will therefore claim our primary attention. Having placed the negative on the retouching desk, and seated ourselves in such a position as to secure ease and comfort, we will begin our work. I will not hold exclusively to my own method, but enumerate several of the most approved systems from which a selection may be made according to the taste or *feeling* of the student. In times gone by, the negatives, as a rule, came to the retoucher ready for working upon. This was in the old wet-plate time. All this, however, has been revolutionised since the almost universal adoption of the dry plate. Now we are obliged to put a medium upon each negative before we can begin our work, as there is absolutely no *tooth* whatever to which the plumbago will adhere. I may have something to say later about the many kinds of medium, but for the present will be content with saying that a medium must be used. This done, we begin by obliterating the apparent blemishes or transparent spots visible on the negative. Some retouchers do this by dotting the negative on these places, and so leaving sufficient plumbago on the film as is necessary to increase its density to that of the surrounding parts. Others adopt a touch something like a comma, others still hold that a continuous system of circles run over the face will produce the desired result. There are some, however (including the most capable retouchers of the day), who adopt lines for their leading treatment. This latter I also hold to be the best, as by it any desired effect can be produced. I do not mean to convey that the lines are straight or rigid; on the contrary, they may be, and generally should be, slightly curved and graceful. They should also follow the lines and muscular drawing of the face, or else we may fail to secure a harmonious result. Let us therefore adopt this latter style in treating the negative before us. Personally (and I follow in the footsteps of a good many better men) I recommend the placing of the negative slightly upon its side, so that we can with comparative freedom make a downward stroke of the pencil that will make a line across the forehead. We must now fill in all irregular and transparent spots and lines (of course, without interfering with the essential markings of the face as before laid down), imparting to these spots and lines the same degree of density as the surrounding portions of the forehead. Of course, if there

should be very marked wrinkles on the forehead they must not be totally taken away, although they may with advantage be very considerably modified. It is not at all necessary or even advisable to completely fill in the various spots and other irregularities we find on a negative, one or two lines, according to size of defect, drawn through them being sufficient. By so doing we secure a double advantage; the slight shade or half tone thus left in will lend a softness, and also, when finished, in part a stippled effect to the picture. This result would be quite impossible if we were to completely block out the spots unless we afterwards made a point of stippling the negative all over. This would naturally entail the loss of much valuable time, and would be likely to impart an over-laboured appearance, without securing the soft and flesh-like stipple so easily attained when the touches are made as above directed. In carrying our work over a face our lines must always take the same direction as indicated by the lines of the skin and position of the muscles. Of course, when these lines run perpendicularly, owing to the contraction of the muscles, we must also modify our touches so as to be in harmony with such conditions. These effects are principally found upon the forehead, and sometimes on the upper lip. Sometimes through the contraction of the muscles hard lines are produced upon the temples, and must not be removed in every face; they may be leading characteristic features without which the likeness would be seriously impaired. If careless, we run the risk of producing one tint over the entire forehead, which would be ruinous, therefore we must be sure to leave indications, however slight, of all these markings, and when the broader effects of light are put in the retention of these indications of form will impart a pleasing and life-like character to our work, which, by other treatment, might be easily lost.

We can now turn the negative somewhat more upright in order, following the direction of the muscle of the orbit, to soften the lines (should there be any) formed around and about the plane of the temples. We can now place the negative nearly upright while we work upon the frontal depression, and also the nose. For the softening and modelling of the furrows under the eyes, certain portions of the nose, and the upper lip, the negative may be turned back so as to facilitate the firm stroke of the pencil, the direction of the stroke as laid down being always strictly adhered to.

The treatment of the labial furrow should be very decided, sufficient density, if possible, being secured at the first application of the pencil, and executed by one long, firm sweep, covering its entire length. Wherever lines running in different directions may cross or meet each other, and necessarily leaving minute defects, it is quite allowable to fill up same with a dot or stipple made with the point of the pencil. We can so proceed, turning the negative constantly as the lines take a different direction, until it assumes an even and delicate appearance all over. The spots being filled up or cut in the first instance, all after strokes used in modelling, &c., should be kept open and equi-distant, or else the work will not be so uniform. A stroke of the pencil must never be made *across* a line; always turn the negative so that at a firm, downward stroke the marking may be satisfactorily filled in. In retouching the neck long sweeping curves should be employed, the negative being almost on its side. In cases where the subjects are very badly freckled, of course there will be necessity for a larger amount of work done with the *point* of the pencil than is above laid down. But naturally every would-be retoucher must use his judgment in such matters, as it would be perfectly impossible to lay down hard-and-fast rules that would govern all the conditions under which we might find every negative. I think with these directions well carried out, we can, as far as *this* method is concerned, lay down the pencil and take up the brush.

It is very seldom that a negative does not require *spotting*, i.e., removing any transparent spots that may be in the film, by whatever cause produced. This is done by filling the spot with a colour (water) made to match the film, or a little neutral tint or violet applied with a finely-pointed sable brush. Should a negative have a great number of very fine holes, like pinholes, the result of some defect in the making of the plate most likely, only spot those in the face, as those in the background and drapery will not be very observable to the naked eye. To attempt to spot these out would be absolute madness, as no matter how fine we might try to spot them we could not do so without making a quantity of white spots visible in the print, and thus entailing more work to afterwards set them right again.

Should the negative be poor in quality and lack brilliancy, and so require helping in the lights, we must matt varnish it and put same in, where defective, with a fine leather or paper stump charged with plumbago. A negative may thus be made serviceable which

otherwise would be useless. I hope these directions will prove sufficient as far as *this* method is concerned, we can then study some of the other systems as practised abroad.

REDMOND BARRETT.

I trust the foregoing on "Methods of Retouching" may *not* be considered as the result of the remarks made by "Free Lance" in a former number of the JOURNAL. I always intended to give them, and their absence was caused by circumstances over which I had no control, although, needless to say, my articles would be incomplete without them. I hope, however, now they are here, that they will (when finished) give that full measure of information which is so necessary to a mastery of the art.—R. B.

PHOTOGRAPHIC LENSES.

[A Communication to the Society of Arts.]

WHILE there are few lenses which cannot in some way or other be made to conduce to the formation of a photographic image, yet does the photographic objective differ *per se* from all others in certain characteristics.

Arriving at a definition of what forms a photographic lens by contrasting it with the object glass of a telescope, we find that whereas the function of the latter is to produce an image of objects which are transmitted axially, or in near approximation to the axis, the former must not only do this but more, for it has to take account of rays transmitted also at considerable obliquity to the axis, and after such transmission has to project these oblique rays to distances proportionately greater than axial ones ere they come to a focus, in order to supply the condition of a flat field. Hence the greater the obliquity of the pencils the more elongated must be the converging beam in order that this indispensable condition be fulfilled.

Again, whereas in visual lenses (by which term I here designate such as are employed in the formation of a merely visual image—as the telescope) it suffices to bring to a focus as many of the luminous or visual rays as possible, or as the irrationality of the spectrum and the glass at command will permit, the photographic lens has to take cognisance not only of these, but of those which, possessing inferior luminousness, have more energetic action. In the correction of a photographic objective for achromatism it is therefore desirable that the yellow and violet rays be united, in order that when a sharp image is seen at the focus on the camera screen, an equally sharp image will be produced on a sensitive plate placed on the same plane, technically known as working to focus, or having the visual and chemical foci coincident. To effect this in an astronomical telescope intended for photography, it is necessary that either the flint and crown elements of the objective shall be separated to some considerable extent, by which the definition both visually and photographically becomes lowered, or to have a supplementary crown glass so adjusted as to secure this condition of coincidence.

It not unfrequently happens that in a photographic lens corrected perfectly to work to focus in the centre of the field, the photographic definition towards the margin will be found to be of a higher class than the visual image. From this we may deduce the fact that a formula by which direct or axial rays are achromatised, does not include the case of oblique rays otherwise than as an approximation.

At this stage it may be well to say that I am to speak of lenses which are formed of optical glass as we find it in commerce at the present time, and shall avoid the realms of conjecture as to the possibilities which may arise from the practical introduction of new kinds of glass which at present are still in the tentative or rudimentary stage. This topic belongs as yet to the optics of the future.

When photography was young, various devices to work with a large aperture, and at the same time to secure sharp definition, were had recourse to. It had been early found that single lenses would not answer, because of their actinic plane of representation being situated somewhat nearer to the lens than that of the visual focus; accordingly the single lens of the camera obscura was supplanted by the achromatic lens of the telescope, the surface of maximum convexity being placed to the outside. Owing to the circumscribed area of definition, the lens was afterwards reversed as regards position and a diaphragm placed in front. The value of Wollaston's meniscus lens was in time duly recognised as a means of securing an extended field; and a lens which I find engraved in a manual by Daguerre, published in 1839, is practically that which is being manufactured in the present year, 1887, subject in some cases to modifications, in others to none. At this juncture, and in the same year, Chevalier, a Paris optician, improved the illumination by combining two achromatic lenses.

But it was reserved for the genius of Professor Petzval, of Vienna, to make the grand discovery of the portrait lens. A year after Daguerre's discovery, the late Voigtländer, when calling upon Pro-

fessor Von Ettingshausen, was asked by that gentleman whether he could determine the refracting and dispersing power of different descriptions of crown and flint glass, because Professor Petzval, who was at that time filling the mathematical chair in the University of Vienna, had made the calculation of a photographic lens which could not be executed in consequence of the qualities of the glass to be employed not being then in existence. Voigtländer, intimating his ability to do this, was asked to call immediately on Petzval, and was given a letter of introduction to that gentleman, accompanied by the observation that by furnishing the means to execute this lens he would render great service to the world and secure for himself a high reputation. The result of the interview that ensued was that Voigtländer furnished the desired information respecting the qualities of the various glasses which formed the foundation of the calculation of two combinations of lenses executed by Voigtländer, one of these being the well-known portrait combination in use at the present time, the other the orthoscopic lens which was not introduced to public notice till 1857. The portrait lens was issued about 1841. Of all lenses extant, it is the one possessing the greatest angular aperture, by which term is understood the diameter of the lens in relation to its focus. In former times, when processes were less rapid than they now are, it is easy to conceive of the impetus given to portrait photography by the discovery of Petzval.

If a plano-convex lens, or one nearly of this form, be inserted in a camera and directed to the light, it will be observed that if the convex side be turned towards the view an image more or less sharp will be formed at the focus, but that the area of sharpness will be exceedingly limited. By reversing the position of the lens, turning the flatter side out, the opposite result is obtained—there is no sharpness anywhere, but a generally better and more uniform image all over the focussing screen. This arises from spherical aberration, the margin of the lens when thus placed bringing the rays to a focus anterior to that effected by the central portions.

The condition for reducing this confused definition to sharpness is that a diaphragm shall be inserted in front of the lens under such circumstances that the centre of the picture shall be formed only by the centre of the lens, no rays finding admission to the margin of the lens but those which come from the side of the view to be delineated, and thus fall upon the surface in a more or less oblique manner. This diaphragm is therefore absolutely necessary with a lens of the nature described, in order to secure flatness of field with good marginal, as well as central, definition. It is therefore necessary that the diaphragm be situated a little distance in front of the lens, because it is only when thus placed that rays are allowed access to the lens subject to the conditions mentioned, those which would mar the sharpness being thus excluded. It must not, however, be imagined that the same effect would be produced by reducing the diameter to the size of the aperture in the diaphragm, for in such a case, while the centre would be sharp as before, the sides would be badly defined.

What has been said of the plano-convex lens is also true of the meniscus. This latter lends itself, by its form, so well to the transmission of rays possessing a great degree of obliquity to the axis, that all lenses which are intended to embrace a wide angle of subject must be of this form; but the spherical aberration being greater in a deep meniscus than in a flat lens, a stop somewhat smaller is requisite in order to its reduction. The deep meniscus possesses properties of a well-marked difference from all others. Those who desire to see the finest exemplification of the so-called "depth of focus" possible to be obtained, have only to procure a meniscus of very deep form, expose its concave side to a bright object, such as a lamp flame, and observe the image. Having got it as sharp as possible, observe to what a great extent the lens may be moved backwards and forwards without the identity of the lamp flame ceasing to be noticed. It is true that it is surrounded by an aura of false light caused by excessive spherical aberration, but the form of the flame itself is still there. In a deep meniscus the diaphragm must be small and be placed comparatively close to the lens. This permits the transmission of a very oblique ray, the incidence of the ray being more normal than in the case of a flatter lens; hence the reason why all wide-angle lenses, whether single or in combination, must partake of the external form of the deep meniscus and the diaphragm be placed near to the lens.

Aplanatism is a somewhat ideal term, and cannot with strict accuracy be applied to photographic lenses. It was originally employed in 1791 by a Scotch *savant*, Dr. Blair, to denote lenses free from spherical aberration in like manner as achromatism signifies freedom from chromatic aberration. Popularly, it is held to designate an objective which gives sharp central definition with its full aperture, no diaphragm being employed. But this even an imperfectly corrected lens will do, provided its diameter be sufficiently reduced. We can, therefore, only talk in this connection by *degrees* of aplanatism, which

would be the better understood if we had a zero from which to start the scale. This zero might be made to equal f , or a diameter equalling the focus; but, at any rate, the term, as it at present exists, has not a sufficiently definite meaning. With this, by way of protest against the mythical expression, I observe that of all photographic lenses extant the old portrait combination is that in which the property of aplanatism, or maximum angular aperture, is greatest. As is the relation of aperture to focus, so is the intensity of the illumination. While a large angular aperture conduces to rapidity, in the same degree is it adverse to penetration, or the property of presenting on a plane surface, and with a degree of definition which satisfies the requirements of the artist, objects situated at various distances. This property of penetration or depth of defining, unthinkingly called "depth of focus," is a power of great value to the photographer, and is induced by means hereafter described. J. TRAILL TAYLOR.

(To be continued.)

Our Editorial Table.

ROUGH'S LEVER WATER SPRAY.

WE have before us a neat and useful addition to the furniture of the developing room, just introduced by Messrs. W. W. Rough & Co. It is intended for attachment, by means of a flexible tube, to the water supply, and consists, as the diagram shows, of a brass tube and rose fitted with a lever stopcock, operated at will by the mere pressure of the finger and thumb. This form of cock is superior to the

ordinary tap, screw down or otherwise, on account of its easier manipulation, and to the numerous forms of "clips" in which an indiarubber tube is constricted by pressure, inasmuch as there is no indiarubber to "perish" and cause the arrangement to leak. The only rubber employed is in the form of a light band, which acts as a spring for the lever, and which may be removed or renewed in a few seconds if the valve is required to remain permanently open or in case of accident. The apparatus is equally adapted for washing negatives or prints, in the latter case the rubber strap being removed to the opposite side of the fulcrum of the lever, in order to keep the valve permanently open. The whole is strongly made, presents no parts likely to get out of order, and will form a decided ornament to the developing table.

HARMONIOUS COLOURING AS APPLIED TO PHOTOGRAPHS.

LONDON: JAMES NEWMAN.

THIS is a new (the fourteenth) edition of a work which has for many years been before the photographic public. It is generally rewritten and revised to present date. Quite comprehensive in scope, the manual, which is of the most practical nature from beginning to end, treats of finishing in monochrome as well as in colours, in water and in oil pigments, in crayons, and by powder colours. Variations of methods to suit special classes of photographs, such as carbons, opals, platinotypes, lantern slides, even crystoleums, are given, together with a concise dissertation on the materials to be employed.

JAHRBUCH FÜR PHOTOGRAPHIE UND REPRODUKTIONSTECHNIK, FÜR 1887.

IN this Year Book, Dr. Josef Maria Eder has got together a large mass of useful and interesting matter, in which he has been aided by various collaborators. It contains several illustrations by woodcuts, zincotypes, and other processes. It is somewhat on the model of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, and is printed in the German language.

THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC FOR 1887.

Edited by J. TRAILL TAYLOR.

THIS well-known annual, which year after year has been increasing in dimensions (attesting its ever increasing popularity), has this year assumed a bulk which is truly portentous.

In addition to a series of short chapters on stereoscopic photography by the Editor, it is enriched by numerous articles written expressly for its pages by the ablest photographic exponents of the day, men

whose names are "familiar as household words" throughout the craft. It also contains those valuable features by which it has so long been distinguished, such as a synopsis of all inventions and improvements by which the past year has been distinguished, several pages of tabulated matter for photographers' reference, a complete list of new patents, formulae for everything required to be known in the practice of the art, together with a compendium of practical receipts extending over many pages.

It would obviously be a breach of professional etiquette, at least in this country, for us to express an opinion on the work, but this does not apply to reproducing what others have said. Among others, the following from Mr. "Luke Sharp," the genial editor of the *Detroit Free Press*—himself an active photographer—may serve as a type of the spirit in which our annual is received by the press:—

"To say that THE PHOTOGRAPHIC ALMANAC OF THE BRITISH JOURNAL OF PHOTOGRAPHY is edited by Mr. J. Traill Taylor is to bestow on the bulky volume about as warm a recommendation as it is possible to give. Wherever the tripod of a photographer is set up, THE PHOTOGRAPHIC ALMANAC is recognised as an authority which it is impossible to do without. Immense numbers of these books are sold in America, although the price there is just double what it is in England. The book contains more than 600 pages, and the photographer, amateur and professional, will find it one of those rare volumes where the advertisements are no less interesting and instructive than the varied and well-written text."

We learn from our publishers that whereas 15,250 copies of the annual have this year been printed, it is their intention that the next year's issue shall reach, and possibly exceed, 20,000 copies.

Department for Inexperienced Photographers.

OVER AND UNDER EXPOSURE.

IN describing the development of a negative, we have assumed that it has hitherto been a case of plain sailing with the photographic tyro. We now proceed to mention some of the rocks or pitfalls which may lie in the way.

If upon applying the developing solution the image takes a very long time to appear, it may be concluded that either a too brief exposure has been given or that the developer is too weak. If the former be the case, it will be signified by the high lights eventually acquiring vigour, the deep shadows being either exceedingly tardy in appearing or failing to come out at all. If, on the contrary, there be no such wide distinction between the lights and shadows, but only a general disinclination of any image to appear, the presumption is that the fault lies with the developer. The remedy in this latter case is to increase the proportion of the alkali, which treatment will never fail in bringing out the details. As we have said before, it is not wise to add so much as to render the development too rapid. Again, it happens with many brands of plates that the presence of alkali in such a proportion as would effect a very quick development may fog or veil the shadows. This is prevented by the addition of two or three drops of a fifteen-grain solution (*i.e.* fifteen grains to an ounce of water) of bromide of potassium or bromide of ammonium, the function of which is to prevent any abnormal deposit on the shadows, or to keep them clean. But owing to the retarding influence of the bromide it must be used sparingly. However, it permits of the employment of a larger amount of alkali than it would be safe to introduce into the developer without such a check upon its energy. It is not quite easy to say precisely how much ought to be added, because of the diversity in character of commercial plates, the best treatment for one brand not being necessarily that for another. There are some plates which require no bromide at all, while others are very liable to fog unless a liberal proportion is present.

Should the image make its appearance with too much equality all over, the shadows coming simultaneously with the lights, it may be taken as evidence of over exposure. In this case it is necessary to act promptly, and at once to pour the developer back into the graduate or cup, and add to the solution a liberal dose of bromide, say four drops or more, according to the circumstances of the case, and having stirred the solution so as to mix it well up return it to the plate. The object of this is to retard the action of the developer upon the shadows, which are thus held in check, while the developing action goes on in the high lights. Under this altered condition of the developer the plate may be subjected to its action for a prolonged period without danger of the shadows becoming fogged. If it is known beforehand, or very strongly suspected, that the plate has received much too long an exposure, then will it be wise to introduce two or three drops of the bromide solution along with the pyrogallol acid previous to adding any alkali at all, as this will in some measure ameliorate the effect of over exposure, while the alkali may also have its action checked by a similar addition of bromide.

What has been here said applies, of course, to pyrogallol development, and it can be readily inferred that by an intelligent adjustment of the component parts of the developer, or perhaps, more correctly speaking, of the alkali and the bromide, a considerable latitude in the exposure is permissible. In all photographic operations development, more than any other, requires the exercise of judgment. Almost everything else can be effected by a hard-and-fast rule, but development is amenable to the intelligence of the operator, an intelligence that must be exercised in the case of every individual plate.

In ferrous-oxalate development there is not the same degree of latitude as in that by pyrogallol acid, although in cases of over exposure the latent or even partially developed image is amenable to the retarding influence of bromide, a few drops of which may, especially at the initial stage of development, be added with marked advantage.

Another factor in facility of development is weakening the developer by the addition of water. But concerning the effects of this we shall have occasion to speak more fully when we come to consider the best circumstances under which to develop snap shutter or instantaneous exposures.

The darkening of the pyro developer, which not unfrequently becomes of a muddy-looking nature after remaining on the plate for a few minutes, may be prevented by sulphite of soda. One of the best ways to employ this salt is to saturate with it the water in which the pyrogallol acid is dissolved. Provided this is done, an aqueous solution of the acid may be made which will keep good for a long time, whereas if it be dissolved in water alone without the sulphite it will decompose with so great a degree of rapidity as to render its preparation in this way a loss.

There are several other additions which may be made to the solution which will prevent the pyro from decomposing, but the consensus of opinion points to sulphite of soda as being the best at present known. It will prove highly educational to the beginner if he will develop a plate without such addition, and note the state in which he finds the developer at its close, and afterwards go through the same operation with a second plate, a liberal proportion of sulphite being mixed with the developer. So clear will it remain in the latter case, compared with the muddiness of the former, that he will be tempted to use it over again on the succeeding plates, which may, in many instances, be done with advantage.

SOCIETY OF ARTS.

At a meeting of this Society held on the 26th ultimo, Mr. James Glaisher, F.R.S., President of the Photographic Society of Great Britain, in the chair, Mr. J. Traill Taylor read a paper on *Photographic Lenses* [see page 72].

Mr. J. Mayall, jun., said he noticed in the early part of the paper a reference to the term *aplanatism*, but it appeared to him that the expression was perfectly well defined by the classical writers on optics. Coddington, the well-known inventor of the lens which bore his name, in a treatise on *Reflection and Refraction of Light* in 1829, defined it as meaning freedom from spherical aberration; and that definition was adopted by Sir John Herschel in his famous treatise on "Light" in the *Encyclopædia Metropolitana*. He could not but think that if in the description of photographic lenses it was used in any different sense—for instance as Mr. Taylor employed it, as meaning the angular aperture of a lens—it was an extraordinary misapplication of the term. Of course he did not attribute the origination of that idea to Mr. Taylor, because it had been more or less used in popular treatises on photographic lenses, and even in Monekhoven's work on photographic optics. Mr. Taylor had referred to a great number of lenses of the old type, many of which were quite obsolete and of no use whatever. On the other hand, he had touched on certain lenses recognised throughout Europe as showing the highest point of excellence which had yet been reached. He took it that since the application of the dry-plate process the old Petzval form, in which an extraordinary aperture was given in relation to the focal length, was practically useless, and every one now used lenses having much less aperture, but where the aplanatism was infinitely more perfect. Reference had been made to the lenses made by Steinheil, in which flint glass was used for the external lenses. That point was taken up by a distinguished mathematician in Paris some ten years ago, M. Prazmowski, the partner of Hartnack, the eminent microscope optician, and it led him not only to utilising flint glass for the external lenses, but also to combining different kinds of flint glass, and he had a very distinct aim, namely, to get rid, in portrait lenses, of the separation in the back combination, which he obtained by using two different kinds of flint glass for each combination, and thus producing a lens with a very short focus, with each combination cemented, so that the reflection given by the surfaces being exposed to the air was got rid of. One of the first lenses thus made was made for him, as the result of a long discussion with Prazmowski, and having brought it to London he thought it would be interesting to Mr. Dallmeyer to see it. He remained about an hour while he tested it, but he was surprised to find that, although he was

known to have considerable technical knowledge, he had not the slightest conception of the nature of the combination,* how the problem of getting rid of the separation of the back lenses was solved, or that the lenses were constructed wholly of different kinds of flint glass, no crown being used. He must confess that even that was now a thing of the past, because it dealt with lenses of the Petzval construction, with great aperture and short focal length, which might now practically be looked upon as out of date. With regard to new kinds of glass for use in lenses, Mr. Taylor seemed to think it was too soon to deal with that question, but he should like to say a word or two on the optics of the future, as they might be developed by new kinds of glass which had lately come into the market. It was perfectly well known in the microscopical world that some time ago one of the most distinguished mathematicians in Europe, who had paid special attention to practical optics, Professor Abbe, of Jena, and his friend, Dr. Schott, had worked out an immense number of experiments with the purpose of providing new kinds of glass which would combine a greater number of lines in the spectrum than had been hitherto combined. Of course that in itself was old, some of our most able mathematicians, such as Professor Stokes, Mr. Grubb, and the late Dr. Robinson, having applied themselves to the problem, any time during the last thirty years; but, unfortunately, their experiments had not ended in any practical result. In this case, however, Professor Abbe being the theorist, and Dr. Schott a practical man, there was a combination which led to a much more exhaustive series of experiments, and the result was that new kinds of glass were really discovered. The earlier experiments they made were not very remunerative; they took a deal of time, and did not lead to any commercial result; but the German Government generously came forward and voted a large sum of money in order that the experiments might be continued. The practical result, so far, had been shown in two ways. First of all, telescopes of considerable aperture had been made by Bamberg, of Berlin, as high as eight inches of clear aperture; and as regards achromatism there could be no doubt he had reached a point which had never been attained before. That, of course, would be shown in practical results by the extremely convenient use of deep eye-pieces. It was well known that when these were used with a telescope in which the chromatism was imperfect, a flare of clouded fringes was produced; but with the new glass the chromatic aberration appeared to be more highly corrected. Turning to a point more interesting to himself, this glass had been used for the improvement of microscopical lenses, and a new series had been manufactured by the well-known optician, Zeiss, of Jena, and there could be no doubt that he had attained more perfect corrections through a larger extent of aperture than in any of his objectives of previous construction; these objectives were, therefore, aplanatic in the sense in which the term was used by our classical writers on optics. As regards achromatism, the superiority over lenses manufactured with the older media was unmistakable. Seeing these results, he could not help thinking that photographic lenses also might be much improved by the use of this Jena glass. He thought photographers had a right to expect from opticians that the necessary energy should be devoted to the problem of endeavouring to utilise these new kinds of glass, and to attaining results in photographic lenses comparable with those which had been obtained in the microscope. He was informed by Professor Abbe that Steinheil had had a good many samples of this glass, and that he had seen his way at any rate to improved forms, and before long he believed there would be an issue of new lenses by Steinheil, made of this material, in which a higher degree of achromatism would be attained with larger and flatter field. If English opticians did not follow in the same path, they would not deserve the support they had hitherto had in England and abroad, where their reputation stood very high indeed. In France, Germany, and Italy, photographers, both amateur and professional, spoke of the quality of English lenses with great respect, and referred to them as being of a somewhat higher standard in the matter of workmanship than almost any produced on the Continent, not in the mere technical execution, but in evenness of quality, so that if a foreigner gave an order to an English firm, he would be almost certain to get a lens of a high standard of excellence. Many people here who had obtained lenses from abroad had not been so successful, and he might say that he had burnt his fingers more than once. If you sent for a lens to Paris you might get a good one, but the chances were you did not.

Mr. Henderson asked what lens Mr. Taylor would recommend, apart from portability, as best suited for an optical lantern.

Mr. Shew asked whether the wide-angled lens shown on the screen by Morrison, containing a single back lens, gave straight lines—was it rectilinear?

Mr. Debenham said he thought justice should be done to the memory of Petzval, and he was sorry to hear his lenses referred to by Mr. Mayall as things of the past, and to hear it said that they were infinitely behind newer combinations in aplanatism. According to Mr. Mayall's view, they were the only truly aplanatic lenses, because by his definition such a lens was one free from spherical aberration, and the peculiar characteristic of Petzval's lens which stamped it as the work of a great genius was the

freedom of spherical aberration. This he obtained by separating the back lenses, and this had always been considered a great mathematical triumph. All portrait lenses, up to the present, had been constructed on that principle, with, in some cases, slight variations, such as reversing the back lens, but the great principle was the separation of the back lens into two parts, one of which had sufficient negative spherical aberration to overcome the entire positive aberration of the system, and so render it aplanatic. Several so-called aplanatic lenses had been introduced since, the first being the single lens of Grubb. Of course, the term merely meant that the lenses were on the way to being aplanatic; perfection did not exist in anything; those that came pretty near to it were entitled to be so called; and for a single lens, Grubb's was a nearer approach than anything before. Then Steinheil—another man whose genius would always be admired whenever photographic lenses were spoken of—introduced a combination which he called aplanatic, because it was so nearly so as to allow of tolerable definition with a focal length of only seven times that of the aperture. The Petzval was four times the length, and sometimes less than that; and if any lenses existed more strictly aplanatic than Petzval's portrait lenses, he should be glad to hear of them. Petzval's served as a model for all lenses, and Steinheil's as the model for a host, for all the opticians imitated him. No doubt, photographers would wonder why their pet lenses were not referred to in such a paper as the present, but the fact was, if those they were in the habit of using were merely copies or slight variations from these leading original types, it would not be proper, in a scientific lecture, to speak of them as originals. One of the most perfectly aplanatic lenses was Steinheil's portrait antiplanat; unfortunately, it lacked perfect flatness of field, more so even than Petzval's, and therefore, though it gave exceedingly fine definition over a small field, it required either a curved plate or to be used only with a very small part of the field to get perfect definition. Perhaps the most ideally perfect photograph which could be obtained would be one in which the curvature of the field was neglected, the plate itself being curved to receive the image. If the reproducing and enlarging processes were as perfect as they were sometimes said to be, the photograph could be taken in this way, but the plate would have to be in the shape of a bowl; it would be difficult to manage, to develop, and so on, and then it would have to be reproduced on a flat plate before it could be made use of for printing, and reproducing processes were not as yet so perfect that this method was at all likely to come into use. One lens Mr. Taylor had shown which he believed had gone out of use, which was much to be regretted, the wide-angle doublet of Ross. Its place had been, to a large extent, taken by another combination of Steinheil's, the wide-angle aplanatic, which certainly had the advantage of greater portability. In covering a large field on a flat plate, the essentials were—first, the field must be flat; therefore, the marginal pencils must be much longer in focus than the central ones, and that condition was fairly fulfilled in the lens in question. Another defect in very wide-angle views arose from the angle of illumination; the corners of the picture received much less light than the centre. The diaphragm opening, looked at from the marginal part of the picture, only represented an oval, having its longer diameter of the same size as the circle which was available for the central part of the field; in the next place, the corners were further removed from the diaphragm, and the image, therefore, was more separated, and thus again the corners received much less illumination than the centre. There was yet a third difficulty arising from the reflection at the surfaces of the lenses.

Mr. Werge said he should be glad if Mr. Taylor could tell him how to determine the focus of a pinhole, as pictures of large and small size could be produced thereby.

Mr. Traill Taylor, in reply, said Mr. Werge was very well aware that, according to the distance of the pinhole from the screen on which the image was received, so would be the magnitude of the image. If it were six feet away it would be large, if only six inches it would be small. The object of the pinhole was to produce an image of the same dimensions as that given by the lens in question, and that could be done by moving the pinhole backwards and forwards until the two images coincided. That was all that was wanted. He made no mention of the focus of a pinhole. Continuing his reply, he said the best lens for a short studio was a short focus lens, and you should get the camera as far away from the object as possible. With regard to lenses for optical lanterns, according to Mr. Mayall, there were none, because it was a thing of the past; but he really thought he could not have been mixing so freely in the photographic world as he ought, or he would know that the Petzval was the lens *par excellence*—the only thing which could be employed for an optical lantern, either for projecting or enlarging, owing to its adaptability. Petzval's portrait lens was the one for the lantern; it was used in the lantern that evening and everywhere else, and he was a little surprised to hear Mr. Mayall say that it was a thing of the past. The most eminent opticians in the world were making them constantly. They might call them universal lens, or the A, B, C, or D lens, or any name they liked, but they were all Petzval lenses, and they were in constant use. The same gentleman had referred to a cemented back. Amongst the first lenses that emanated from the factory of Voigtlander were lenses with cemented backs; they were triple compound lenses of enormous aperture and very short focus, capable of working, as was facetiously said, in a coal cellar. Voigtlander took out a patent for that again a few years ago, and portrait lens with cemented backs were things of the present day. Mr. Mayall

* There must be some misapprehension here on the part of Mr. Mayall. The late Mr. Dallmeyer was far too good an optician not to have realised the precise nature of the lens the moment he got it in his hand. We know as a fact that at the time alleged Mr. Dallmeyer was intimately conversant with the whole problem of cemented back lenses, and it is well known that also at the time alleged, and even ten years anterior, lenses "constructed wholly of different kinds of flint glass" were regular articles of commerce.—Eds.

had also referred to lenses being made wholly of flint. When he described Steinheil's invention, he characterised it as being made of two kinds of flint glass, the denser element outside; and all the lenses of the present day characterised by the term "rapid," with the exception of the one he had spoken of as being American in inception, were made with two kinds of flint glass, the denser element outside.

The Chairman, in proposing a hearty vote of thanks to Mr. Taylor, said he hoped the new glass would cause so great an improvement in photographic lenses, that the next time they had a paper from Mr. Taylor he would include it, and slow the progress which had been made.

The vote of thanks was carried unanimously, and the meeting adjourned.

RECENT PATENTS.

APPLICATIONS FOR PATENTS.

No. 1465.—"Improvements in or connected with Photographic Cameras and the Sensitive Media for Exposure therein." W. NORTH and K. L. NORTH.—*Dated January 29, 1887.*

PATENTS COMPLETED.

IMPROVEMENTS IN THE STANDS OR SUPPORTS FOR PHOTOGRAPHIC CAMERAS. No. 2423. ARTHUR RAYMENT, 36, Beatrix-road, Finsbury Park, Middlesex.—*February 19, 1886.*

This invention has for its object improvements in the top part of the tripod stand or other support for photographic cameras, whereby the camera can be readily moved into any required position and placed at any desired angle.

In carrying my invention into practice I construct the top of a tripod, or other stand or support in two parts, hinged so that they will fold or lie closely together; for convenience of description I will call one part the "upper" and the other part the "base."

The special use of these parts is that whilst the base part is attached to the legs, clip, or other support, the upper part (acting upon hinges) may be adjusted so as to enable the operator to turn the camera to take a photograph at any desired angle or position.

Another motion is provided where the camera is oblong shaped (so as to maintain approximately the centre of gravity of the camera during or when ready for an exposure), the camera being attached to the upper part of the aforesaid tripod top, which part is hinged to a sliding piece arranged in and combined with the base part; the camera is slid or drawn back on this piece (which is adjusted or fixed at the desired point by a suitable spring catch) and then changed from the horizontal to a vertical position, or *vice versa*, thus obviating the weight of the camera when so changed causing unsteadiness or overbalancing by being thrown outside of the centre of gravity of the support or stand.

The relative positions of the parts are secured at any angle desired by means of a suitable spring between the two parts, or by a slotted rod fixed to one part and clamped on the other by a set screw, or by a piece of wood or metal arranged and forming an arc between the ends of the two parts, and adjustable by a set screw, or by any other convenient method.

A hole or recess is formed in the "base," so as to allow the screw, which serves to secure the camera to the upper part, to pass through when the two parts are lying closely together.

Any suitable material may be used in the construction of the several parts, which may be varied or modified, if desirable.

IMPROVEMENTS IN OPTICAL LANTERNS.

No. 3805. HENRY MARTYN WHITEFIELD, 54, Yarrow-street, Manchester, and SAMUEL WASHINGTON, 19, Radnor-street, Manchester.—*March 18, 1886.*

This invention relates to optical lanterns. The object is to effect a rapid change of the pictures exhibited on the screen by a single lantern and by means of a novel arrangement for shutting off the light, to do this without the changing of the picture being visible, and to prevent any possibility of vibration or movement of carrier during the insertion of a new slide.

The invention consists in fitting in the front part of the lantern, between the condensers and objectives, a suitable shutter or shutters worked from behind the lantern by means of a shaft running from front to back, and having a handle fitted to it. A cam and crank fixed on the end of the shaft closing the shutters and opening them again. Whilst the shutters are closed, a lever acted upon by the crank is made to pass forward a double carrier, thus changing the picture; the carrier is now held firmly in position by a powerful spring and the shutters are opened again, when the new picture appears upon the screen. These combined movements are effected by one half turn of the handle, and, being almost instantaneous, the sheet is darkened only for a moment, besides which, the ludicrous effect of landscapes, &c., sliding across the sheet, produced by changing the pictures in the manner that has hitherto been customary, is entirely avoided.

The claims are:—1. The combination with the shaft passing from the back of the lantern of the cam, levers, springs, and shutters or fans, substantially as and for the purposes described. 2. The combination with the shaft passing from the back of the lantern of the cam, hinged flap, and springs for holding the carrier in position, substantially as and for the purposes described. 3. The combination with the shaft passing from the back of the lantern of the crank and lever for changing the carrier, substantially as and for the purposes described. The specification is illustrated.

We are requested to state that Mr. H. H. O'Farrell, who has lately been making some experiments on the sulphuration of platinotype prints, will exhibit his results and read a short paper on the subject at the ensuing Conference of the Camera Club, at the Hall of the Society of Arts, on Tuesday next.

PRESENTATION OF A TESTIMONIAL TO JAMES GLAISHER, F.R.S.
LAST Monday night a large number of the members of the Photographic Society of Great Britain presented Mr. James Glaisher, F.R.S., the President, with a marble bust of himself, as a mark of the esteem in which he is held by them; the event took place at a dinner at the Holborn Restaurant, London, at which a large number of ladies and gentlemen were present, all the seats at five or six long tables being occupied.

Mr. W. S. BIRD, who took the chair, expressed regret at the absence of Captain Abney, who was to have occupied that position, but was prevented by the serious illness of a member of his family. He then read the circular which had been posted to the members, proposing that the testimonial should be presented, and setting forth the long and valuable support which Mr. Glaisher had given to the Society by his long years of earnest work; he next read letters from various noted photographers who were unable from illness and other causes to attend, including, among others, Captain Abney, Colonel Stuart Wortley, Messrs. H. P. Robinson, Henry White, John Spiller, Frank Bishop, J. Stuart, H. Trueman Wood, and Joseph Paget. The speaker said that Mr. Glaisher had furthermore done much good to the Society by reason of his great eminence in the scientific world. A reference to the catalogue of the Royal Society proved that he had contributed to that Society no less than fifty memoirs, the majority of which were on the subject of meteorology, for Mr. Glaisher had been for forty years the chief of the Meteorological Department of the Royal Observatory at Greenwich. He had made twenty-nine balloon ascents for scientific purposes, to take observations on the following points, namely:—1. Temperature of the air and its hygrometrical condition at different elevations. 2. Temperature of the dew point, also, as bearing on sanitary questions in relation to living on great heights or quartering troops. 3. The comparison of the aneroid and mercurial barometers. 4. The electrical oxygenic conditions. 5. Vibrations of a magnet on the earth and at various distances from it. 6. Height and character of clouds. 7. Rate and direction of currents of wind. 8. Observations on sound, and other memoranda of aerial physics likely to serve the general principles of the science of meteorology and lead to practical and beneficial results. In one of his ascents, when, on September 5, 1862, Mr. Glaisher started from Wolverhampton, the barometer indicated 29,000 feet of elevation, he passed on the way through a cloud 8000 feet deep and so dense that the balloon could not be seen from its own car. Of this voyage Mr. Glaisher reported:—"I asked Mr. Coxwell to help me to read the instruments, as I experienced a difficulty in seeing. In consequence, however, of the rotatory motion of the balloon, which had continued without ceasing since the earth had been left, the valve line had become twisted, and he had to leave the car and mount into the ring above to adjust it. At this time I looked at the barometer and found it to be ten inches, still decreasing fast; its tone reading therefore was nine and three-quarter inches, implying a height of 29,000 feet. Shortly afterwards I laid my arm upon the table, possessed of its full vigour, and on being desirous of using it I found it powerless—it must have lost its power momentarily. I tried to move the other arm and found it powerless also. I then tried to shake myself, and succeeded in shaking my body. I seemed to have no limbs. I then looked at the barometer, and whilst doing so my head fell on my left shoulder. I struggled and shook my body again, but could not move my arms. I got my head upright, but for an instant only, when it fell on my right shoulder, and then I fell backwards, my back resting against the side of the car, and my head on its edge; in this position my eyes were directed towards Mr. Coxwell in the ring. When I shook my body I seemed to have full power over the muscles of the back, and a considerable power over those of the neck, but none over either my arms or legs; in fact, I seemed to have none. As in the case of the arms, all muscular power was lost in an instant from my back and neck. I dimly saw Mr. Coxwell in the ring, and endeavoured to speak, but could not; when in an instant intense black darkness came, the optic nerve finally lost power suddenly. I was still conscious, with as active a brain as at the present moment while writing this. I thought I had been seized with apoplexy, and that I should experience no more, as death would come, unless we speedily descended: other thoughts were actively entering my mind, when I suddenly became unconscious as on going to sleep. I cannot tell anything of the sense of hearing; the perfect stillness and silence of the regions six miles from the earth (and at this time we were between six and seven miles high) is such that no sound reaches the ear. My last observation was made at 1:54 at 29,000 feet. I suppose two or three minutes fully were occupied between my eyes becoming insensible to seeing fine divisions at 1:54, and then that two or three minutes more passed till I was insensible; therefore I think that took place at about 1:56 or 1:57. Whilst powerless, I heard the words, 'Temperature' and 'Observation,' and I knew Mr. Coxwell was in the car speaking to me, and endeavouring to arouse me; therefore consciousness and hearing had returned. I then heard him speak more emphatically, but I could not see, speak, or move. I heard him again say, 'Do try; now do.' Then I saw the instruments dimly, then Mr.

Coxwell, and very shortly saw clearly. I rose in my seat and looked round, as though waking from sleep, though not refreshed by sleep, and said to Mr. Coxwell, 'I have been insensible.' He said, 'You have; and I, too, very nearly.' I then drew up my legs, which had been extended before me, and took a pencil in my hand to begin observations. Mr. Coxwell told me that he had lost the use of his hands, which were black, and I poured brandy over them." He, the Chairman, was pleased to say that there had been 133 subscribers to the testimonial, and pleasing letters had been received from some members who were unable to do, financially, so much as they desired; he was also glad to say that they had a poet in the Society who had written the following lines in honour of the President and of the event of that evening:—

"Yon marble bust reveals the face of one
Whom Science claims, for battles fought and won;
Yet not in deadly conflicts, such as those
Which fill this world with pain and mighty woes;
But in that higher life, where men of mind
Serenely toil to benefit mankind.
There, 'midst the truest heroes of our race,
The name of GLAISHER holds an honour'd place;
And here we fitly celebrate to-night
His reign o'er those whose kingdom is the 'light.'
Well has he governed, with strong, guiding hand,
Where 'Truth' and 'Equity' both take their stand;
Then honour give for many years thus spent,
And greet we him—our worthy PRESIDENT."

The bust bore the following inscription upon a silver plate on its pedestal:—
"Presented to James Glaisher, F.R.S., etc., by Members of The Photographic Society of Great Britain, in recognition of eighteen years' devotion to its interests as President and as a token of their affection and esteem. January 31st, 1887."

Mr. JAMES GLAISHER, in returning thanks, said that he had a difficulty in finding words to express his feelings. Years ago, Dr. Diamond, and others, had pressed him very much to be put into marble. In its early days the Photographic Society had been a fashionable one; Sir C. Eastlake was then its President, and a meeting of the Society was never held without a *recherché* banquet before it began; the then Secretary had a salary of £200 a-year. When fashion left the Society, it fell into debt; the Secretary still claimed his salary, and the printers threatened him (Mr. Glaisher) with an action if he did not pay their bill of a few hundred pounds. But the Council and members worked and worked, until at the present time they had a balance on the right side, and they no longer had debt to check their progress as it did in the past, when he came to hate the words "No funds." Photographic portraiture had brought pleasure to thousands of homes, and photography was now the handmaid of astronomy and of the other sciences. The exhibitions of the Society had helped to keep every one up to the mark; although at the last one there were no exhibits from Bedford—father or son, none from England, none from Robinson, none from Blanchard, it yet showed progress in every department. Especially had photography improved in its art aspects. He should like to see photographic energy more concentrated, for science had been a bad housekeeper, incurring a variety of expenses which might have been lessened by all pulling together, and he hoped that photographers would not follow the example; union was wanted, and it was desirable the photography should have a home of its own. He had been pained to read in THE BRITISH JOURNAL OF PHOTOGRAPHY that the frames sent to the last exhibition had been scratched; he had seen the pictures handled there as tenderly as a mother would handle her new-born babe, and an endeavour had been made to take every care. Mr. Cocking had made inquiries into the matter, and discovered the complaints to be well founded. Then it came out that they were but tenants, and that in the building was a dread mid-passage through which the pictures had to be carried; what injury they may have had there he knew not, but next year the Society must give protection against such damage. The Society had now a little in the Consols and a balance in hand, therefore it could now have its library, its laboratory, and a number of other conveniences. He was glad to see such a large number of ladies present; under the presidency of the Chief Baron at King's College there were always ladies present at the meetings of the Society, and he hoped that more would come as members or visitors. The now unveiled bust seemed to him, at that distance from it, to be an admirable one; it would never have been executed had it not been for his friend on his right, the Rev. Dr. Lausdell, who had travelled in Siberia, Bokhara, and other far-away places. The sculptor, Mr. Toft, threw his heart into the work, as he could see by his looks at the first one or two sittings; so he sat for him as frequently as he could, and when he left London the bust was finished below the chin by the aid of photographs. His time as President of their Society was probably limited, but what they had done that evening would encourage those who came after him, and he returned his warmest thanks to all.

Mr. Glaisher here sat down amid loud applause, the music and the company then striking up "For he's a hearty good fellow."

Mr. FRANCIS COBB then proposed the health of the Chairman, saying that once a Member of Parliament, aggrieved by an opponent, complained:—"Does the honourable member think that I can be in two places at once, like a bird?" Well, the Society had caught that Bird, and he had done all the real work of the testimonial committee.

Mr. W. S. BIRD having returned thanks.

Mr. PAYNE JENNIX proposed "Success to Photographic Art and Science," saying that he was in special sympathy with the artistic aspects of photography. The Society wanted a gallery of its own, so the next thing as Englishmen to do, was to have it.

Mr. JOSHUA SMITH, Ex-President of the Photographic Convention of America, responded.

The CHAIRMAN next proposed the health of Mr. Albert Toft, the sculptor of the bust, who, he said, was a rising young scholar, who was winning golden opinions from the lovers of the art, and had been very successful at exhibitions.

Mr. TOFT responded that he had taken a special pleasure in chiselling the

bust before them, and should always feel grateful to the Photographic Society, for helping him over the first stepping stones of his career.

Mr. W. ENGLAND proposed "The Ladies," to which Mr. G. L. Addenbrooke responded.

Several glees were sung during the evening by Messrs. Blanchard, Pearce, and Cocking, among them being the following, written for the occasion, and adapted to well-known music:—

"In the merry old times of photographers,
When the wet silver bath ruled here,
(They'd collodion as well,
As their chronicles tell),
And got fogged every day in the year.
"One day, when their baths went awfully wrong,
They carried them into the light,
And commanded the Sun,
(As he'd hitherto done),
To make all those baths clean and bright.
"But old Sol, in a pet, roll'd out a remark,
That the time for such work was all over;
And he foamed and he roared,
'We're not in accord,
As you all very soon will discover.'
"Then the President summoned his Council so wise,
'Here's a pretty to-do!' quoth he;
'We're on the wrong path
All along of that bath,
And old Sol's in a flat mutin-ee;
To quell revolution,
We'll drink the solution,
And go in for gelatin-ee.'"

Recitations and songs were also given by Messrs. W. Cobb, Valentine Blanchard, A. Cowan, sen., A. Cowan, jun., and by two professional singers, Mr. Arthur Thomas and Mr. Laird Donald. The pianist was Mr. Alfred Smythson.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

ON Thursday, January 27, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. J. Trail Taylor presided.

Mr. A. L. HENDERSON said that by the use of yellow glass he had succeeded in getting as good results upon ordinary plates as Mr. B. J. Edwards did with orthochromatic plates, but the latter "scored" against him in photographing deep blue-black discs upon a yellow ground. He exhibited the results he had obtained.

The CHAIRMAN stated that Mr. Bierstadt, of New York, had long been in the habit of photographing paintings by interposing the proper kind of yellow glass; the time of exposure had to be lengthened.

Mr. HENDERSON had found the quality of Mr. Edwards's plates to be very good indeed; they were a little slow, and they gave good negatives. Mr. Edwards had said that they were not stained; he had found, however, that when they were moistened and warmed a distinct pink stain put in an appearance.

The CHAIRMAN knew a man who had been trying to make plates orthochromatic with red ink, which was usually composed chiefly of eosine and gum arabic.

Mr. A. MACKIE had heard that Mr. Friese Greene used the colouring matter of the beetroot for the purpose.

Mr. W. M. ASHMAN said that Mr. Friese Greene had told him that the beetroot extract had a very good effect.

Mr. HENDERSON called attention to a circular of "Cellerier's Syndicate, Limited," which related, he said, to a process as old almost as photography itself, and consisted chiefly in colouring photographs from behind. Some such, produced by Léon Vidal, were on view in the Paris Exhibition many years ago. Cellerier's Syndicate was trying to raise a large amount of capital.

The CHAIRMAN thought Cellerier's process to be a coloured photograph at the bottom with a thin photograph upon the top.

Mr. HENDERSON read the claims in the Cellerier patent, which was dated 1885.

The CHAIRMAN thought that the first patent for that kind of thing was taken out in 1865 or thereabouts by Ashton, of Birmingham; he chromo-lithographed in colours, then printed a photograph thereupon, a picture in colours being the result. Another process, something like Cellerier's, had been used by those persons who induce ladies of limited means to give a few guineas for tuition. Madame Una Howard years ago practised a process in which a sheet of paper was printed in pretty strong colours, and placed upon that was a photographic print rendered translucent; a very pretty effect resulted. The changes rung upon this method of producing photographs had been innumerable.

On the motion of Mr. ASHMAN, it was resolved that Mr. Henderson be appointed a committee of one to make inquiries about the Cellerier process, and to report to the next meeting.

Mr. A. COWAN exhibited a gelatino-chloride print developed with magnificent blacks upon opal glass without any toning; ferrous citrate was used as the developer; before it was applied there was no visible image on the plate.

The CHAIRMAN and Mr. ASHMAN thought the process to be very valuable.

Mr. J. HURBERT said that when he read his forthcoming paper to the Association on collodio chloride printing he hoped the members would bring forward for discussion all the reasons they could against the process being introduced.

Mr. ASHMAN said that whenever photographers had tried practically to introduce new processes the public had insisted upon still being supplied with albumenised prints. Twenty years ago collodio-chloride prints were turned out in America by the million.

The CHAIRMAN said that very few were turned out there now, and that Mr.

Jabez Hughes, after producing them for a time in this country, gave up the attempt.

Mr. F. W. Edwards was elected a member of the Association, and the proceedings closed.

DERBY PHOTOGRAPHIC SOCIETY.

THE annual *conversazione* of this Society, held in the St. James's Hall on the 26th ultimo, was very successful. The side walls of the building were covered with beautiful specimens of photography, obtained by different processes, while the centre of the room was occupied by other photographs, various kinds of cameras, and other appliances.

Captain ABNEY opened the proceedings by delivering a brief address. He said that he believed that in the human breast there was always a yearning either for science or art. If any one wished to become a scientific man he could not do so without knowing something about photography. It was not everybody who could draw and paint, but yet they might possess a true artistic feeling, and photography was the legitimate expression of a yearning for art—that yearning by which they expressed on a plate that which they failed to express by means of the fingers. Again, those who had not time to learn either drawing or painting should take to the camera, and thus express their artistic feeling by means of the plate. A great deal more was now known than formerly about the sun and moon, and the star depths which the photographic plate had shown to exist beyond what they could see. Photography was an unerring recorder of facts; it possessed no personal bias or error, and if they wanted to be correct they must photograph what they saw, and not trust to impressions. Captain Abney concluded his remarks by giving ten reasons why all present should become photographers and join the Derbyshire Photographic Society. The first, and perhaps the most important reason, was that it would give them outdoor exercise, which, to persons leading a sedentary life, was very valuable. The second reason was that the art trained the eye, and they could never thoroughly appreciate nature until they had received that training. Another reason was that it trained the hands, making them neat and skilful. It also taught patience, a most important principle. It also taught people to think, and he believed that any person who passed through life without it was not fit to live. Photography also gave rise to a healthy and unselfish competition, as was evident by the large collection of splendid pictures which now adorned the walls of that hall, and was an unerring register of facts. The practice of photography was a sensible amusement; it was the first step to chemical and physical science; and, lastly, if they tried the art they would like it.

After Captain Abney's address a musical programme was gone through, and several slides were shown during the evening.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The usual monthly meeting of this Association was held on Thursday, the 27th ultimo, at the Royal Institution, Colquitt-street.—The retiring President, Mr. P. H. Phillips in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. PHILLIPS then introduced his successor for the current year, Mr. George H. Rutter.

A cordial vote of thanks was given to the retiring officers.

The following gentlemen were unanimously elected members of the Association:—Messrs. William H. Coward, W. Tonkinson, and W. Priestnall.

The Treasurership having been declared vacant, owing to a recent decision of a special general meeting, Mr. Joseph Earp was elected Treasurer for the current year.

Dr. Kenyon exhibited a negative on an Eastman "stripping film" mounted on glass. Originally the film was on paper and was exposed with the roll of which it formed a part in the roller slide. Development was effected with ferrous oxalate in the usual way. After fixing and a brief wash, the film still on its paper support, so far treated as any other paper negative, was then simply removed from the washing water in contact with a clean piece of glass a little larger than itself and was placed in a warm room and allowed to dry thoroughly. Dr. Kenyon placed the glass, with the paper and film now firmly adherent, in water about 100° temperature, and soon afterwards poured upon it water nearly boiling; in two or three minutes the paper was thoroughly loose and was removed without the least difficulty. The plate with the film still adherent was then rinsed with the hot water. The negative then only required drying, in which condition it could be used for printing lantern slides and for enlargements, or, being a reversed negative, for printing by the carbon process. Used in this way the stripping films involve no extra labour worth speaking of as compared with glass negatives, whilst the convenience of paper in the field is fully taken advantage of. If the negative be left in the state as above described there are inequalities in the free surface which will be completely filled up and a perfectly polished result obtained if the stripping process be completely carried out; this involves the superposition of a sheet of gelatine one side of which is matt and the other polished, consequently when the film is detached from the glass each side is then polished, and the result is as perfect in every respect as if taken on a glass plate. Dr. Kenyon exhibited films in both conditions, and the demonstration, which was perfectly successful, excited considerable interest.

Mr. Mayne exhibited Sands & Hunter's book for holding dry plates, also Mason's trough for use as an alum bath.

The new President, Mr. Rutter, made a few introductory remarks upon taking office, postponing, however, any formal address until next meeting, as a long and interesting paper by Mr. Beer was expected to fill up all the remaining time.

Mr. A. W. BEER then read his paper, entitled *A Holiday in the North Riding*, which was illustrated by nearly one hundred lantern slides. Commencing with Whitby, with its ancient houses, magnificent abbey, ruins, and remains of former prosperity, Mr. Beer gave a vivid description of the quaintness and artistic beauty of the secluded villages in the neighbourhood, such as Runswick, Staithes, and Robin Hood's Bay, the very names of which are scarcely known, and yet which abound with picturesque subjects. He then

took his audience through the Vale of Pickering to Helmsley, thence to Rievaulx, with its fine abbey, Byland, Coxwold, and finally to Durham, both his description and illustrations being attentively followed by an interested audience. The lantern slides, a few of which had been furnished by Mr. Boothroyd, were of a high class, and the lantern was efficiently operated by Mr. Phillips.

A few miscellaneous slides, the work of the members, were exhibited, and the meeting closed at a late hour with enthusiastic votes of thanks to Messrs. Beer and Kenyon.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

At the meeting held at Myddelton Hall, Islington, Tuesday, February 1, Mr. J. Traill Taylor, President, in the chair.

Mr. A. Mackie showed an unexposed gelatine plate made by him early in 1876; he also showed a negative taken on a similar plate about the same date. The plate was, according to modern ideas, far too thinly coated, yet the negative was of ample density.

Then Mr. Healy showed results produced from a Wratten & Wainwright's gelatine plate made in 1878 but exposed and developed in 1886. The plate had deteriorated but slightly, an iridescent stain which extended to a depth of about half an inch from the margin being the only fault.

The PRESIDENT observed that the subject of the deterioration of gelatine plates by keeping was one which might with advantage be brought specially before their notice on another occasion. It was well known that by various reagents the nature of the silver salt in a sensitive film could be changed. By treating a developed image with bichromate of potash and hydrochloric acid the deposited silver would be converted into chloride, and so in other directions. He inquired if any one present had made a systematic attempt to restore to something akin to their original quality plates which had become deteriorated by keeping.

Mr. F. W. HART said that he had successfully treated negatives showing this defect by immersing them in chlorine water, thereby converting all the silver compounds in the negative to chloride of silver; after this treatment the plate was exposed to light and then redeveloped with ferrous-oxalate developer. With regard to treating unexposed plates for this complaint, he thought the application of bromine water would probably prove a remedy, as the sulphur compounds of silver, to the formation of which this phenomenon was due, would be converted back into bromide of silver.

The PRESIDENT thought the subject would form a good one for discussion at a future meeting.

Mr. MACKIE having passed round two negatives which showed bands of insensitiveness, due, he explained, to the plates having been kept for some time in the slides before use, and the material of which the hinges were formed having had some chemical action, several members related similar experiences, while others instanced cases in which plates had been kept in the slides for long periods without harm.

Mr. HART spoke of a case where the hinges of the dark slide had caused the opposite result. In this case the developed negative showed a reduction of the silver.

Mr. COX showed a negative in which one of the upper corners was thinner than the other portion. He could not account for this, as there was a clearly-marked boundary which ran in a diagonal direction. It was suggested that the plates had been packed with a sheet of paper between each pair, and that in this case the corner of the paper had become folded back.

A discussion then took place on the action of the contact of writing and of printing inks on sensitive plates, in which Messrs. E. Clifton, G. Smith, and others took part.

Mr. Reader passed round some of Tylar's metal dark slides. These were of less bulk than wooden ones, but were considerably heavier.

The PRESIDENT announced that at the next meeting Mr. Coventon would show some examples of the work of the late Mr. Henry Cooper, a well-known member of the original North London Association.

The next meeting of the Society will be held on Tuesday, February 15. The President will give an address on *The Lenses in Everyday Use*. Visitors are invited.

Correspondence.

THE CAMERA CLUB CONFERENCE.

To the Editors,

GENTLEMEN,—Will you allow me to make known through the JOURNAL the following details in connection with the Photographic Conference organized for Tuesday next, the 8th of February, under the auspices of the Camera Club?

The Conference will be held in the Hall of the Society of Arts, John-street, Adelphi, by permission of the Council, and the proceedings will be opened at 11 a.m. by the President of the Club, Captain W. de W. Abney.

The communications to the meeting will be as follows, and in the following order:—

From 11 a.m. to 1 p.m.:—

1. On Studies. W. Adcock.

2. Testing Sensitiveness of Plates. W. K. Burton.

3. Certain Features in connection with Enlarging. J. Traill Taylor.

From 1 to 3 p.m. there will be an adjournment to inspect the exhibition of apparatus and of members' pictures at the rooms of the Club.

The Conference will be resumed at 3 p.m. and continued till 5 p.m. for the reading of the following papers:—

4. The Sulphuration of Platinotype Prints. H. H. O'Farrell.

5. Isochromatic Photography. W. H. Hyslop.

6. (Subject not yet announced). Captain W. de W. Abney.

7. Rational Development. A. Pringle.

All interested in the subjects to be dealt with at the Conference are invited to attend by introduction of a member or by card. Formal tickets of invitation can be obtained on application to the undersigned.

In the evening at 8 p.m. the first Annual Dinner for members and friends will be held at the Holborn Restaurant.

At the same hour on the previous evening, Monday, 7th February, a special smoking concert will be given at the Club, and on the Thursday, 10th February, the evening meeting will be devoted to an explanation and discussion of the apparatus on show in the rooms.—I am, yours, &c.,

G. DAVISON, Hon. Secretary.

Camera Club, 21, Bedford-street, W.C., February 1, 1887.

CYANINE IN ORTHOCHROMY.

To the Editors.

GENTLEMEN,—I find from the report in your JOURNAL of last week, that it was asked at the meeting of the Photographic Society of Great Britain if any one had used cyanine for colouring plates for the orthochromatic process? Cyanine is used by Dr. Vogel in his patented process, and forms with chinoline the chief ingredient of the colour sensitiser of the "Dizaline" plates.—I am, yours, &c.,

J. R. GORTZ.

19, Buckingham-street, Strand, W.C., February 1, 1887.

YELLOW STAINS ON NEGATIVES.

To the Editors.

GENTLEMEN,—In the "Answers to Correspondents" column of your issue of 21st January, is a statement from "Geo. Smith" of his unsuccessful efforts to remove yellow stain from negatives which, he says, "if the stain were removed would give good prints," and you suggest that "perhaps some reader can assist."

For removal of the stain I can suggest nothing, as my own experiments in that line were, more or less, failures; but this I can state, with absolute confidence, as the result of my own experience, namely, that after trials of the various leading developers, with and without sulphite, I was reluctantly forced to the conclusion that the development without sulphite—giving a clear yellow stain to the negative—results in "the perfection of printing," as was said by a strong advocate of soda a few years ago. I say "reluctantly" because, without doubt, the developer without sulphite is much more finger soiling, and therefore disagreeable in manipulation.

If an amateur wishes only to make the prettiest negatives, by all means let him use the developer which will give the blue-black, or the blue-grey tones; but if he works for strong prints, and, above all, for the richest tone, which in my opinion is that which I will call purple-black—but tone, I am aware, is a matter of taste—he will not be too shy of the "greenery-yallery" stain in his negative, assuming it to be good in all other respects.

I enclose a few of my smaller prints, being remainders, and not the best, but taken from distinctly yellow negatives, developed with either pyro-potash or pyro-soda, or some combination of those alkalies.—I am, yours, &c.,

J. G. R.

P.S.—I have about concluded to give up the pastime, chiefly because I find it so difficult to get first-class sensitised paper. Samples almost always work (and tone) easily and well, but "bulk" subsequently ordered is very prone to disappoint.

A USEFUL HINT.

To the Editors.

GENTLEMEN,—Will you kindly allow me, through the medium of your valuable JOURNAL, to bring before the notice of photographers generally, and especially those engaged in platinotype printing, the fact that very many faulty prints in platinum with feeble shadows and discoloured whites may be avoided by using one of Mr. Fletcher's new brass burners? In common with many others, who for years past have been accustomed to use the atmospheric stoves made of iron in the chemical laboratory, I have often been troubled with the quantity of rust formed, and the constant care and watchfulness needed to prevent error and mishap in the results arrived at, through small particles of rust—that are constantly falling off the burner on to the bench, &c.—becoming attached to the fingers or other pieces of apparatus, and thus unknowingly carried into the solutions in use. So important is it that no particle of iron should come in contact with the oxalate developer, that the Platinotype Company caution one against using the enamelled iron developing dish after the enamel has once cracked. Having recently taken up with platinotype printing, this fruitful source of failure induced me to write to Mr. Fletcher to ask him if he would assist platinum printers by casting some stoves in brass. This he consented to do, and the stove I have received from him, "No. 16 Star," answers the purpose admirably. So perfectly is the heat under control, that you can keep any quantity of solution—from one quart to one and a quarter gallons—at any constant desired temperature. Having experienced myself the comfort and cleanliness in using such a burner, always clean, and free at all times from rust, I thought I would make known to your readers that such could be procured.—I am, yours, &c.,

JOHN DAVIES.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

To the Editors.

GENTLEMEN,—Mr. W. S. Bird's attack on me in THE BRITISH JOURNAL OF PHOTOGRAPHY of this week is sharp, but, I think, not ill-natured, and it is signed by an office-bearer of the Society. The first part of his criticism is, I venture to say, conducted on a line entirely wrong. My personality—whether I am a "Sir Oracle" or not—is a matter that has no bearing on the question whatever. The point is not whether I am a conceited fool, but whether the Society is or is not conducted as it ought to be. Mr. Bird, as a private individual, is of opinion that the Society is all we can desire. I hold a different opinion, and I suppose I am at liberty to "ope my mouth." A good many other people are of my opinion if the truth were known, though only a few have expressed their sentiments as I have done—a fact easy to understand when we see how I am attacked. This reticence on the part of other persons places me in a very difficult and delicate position; I dare not even hint at the names of persons in high positions in the Society who are entirely with me in heart, though it does not suit them to join me in public.

Mr. Bird is rather unfair when he confronts me with one particular jury—that of last year. As soon as I saw the list of jurors chosen I said that a better jury could not be found. Mr. Bird quotes me correctly—"the juries"—and straightway proceeds to name the jury for 1886. This seems to me somewhat arbitrary. I hope that the jury of 1886 were all perfectly satisfied with the awards; I hope that the awards were made with tolerable unanimity. In my year the numbers allotted to certain pictures varied from 9 to 0. I do not call that unanimity, nor even tolerable unanimity. One juror or two can, by the present system of voting, take away from a picture all chance of an award, however high the votes of other jurors may be; and I have known this done on a simple matter of *dogma* regarding the style of mounting.

Mr. Bird's summing up of what he calls my "opinion" is not justified by what I wrote. I never said the Society ought to "conduct an Exhibition in London only to exalt the work of its own members." What I suggested was, that members should have the first claim to a limited area of good wall space. A very different affair from Mr. Bird's rendering of my words.

Mr. Bird states, what may be true enough, that pictures on gelatinobromide are sent in by the score that have no just claim to be hung. There is another view of the case that may be taken. "Carbon enlargements" are produced with excellence by very few firms, perhaps, I may say, by two firms only, yet we have over twenty large frames in one Exhibition by one firm alone. This may be very representative of a firm, and highly flattering to that firm, but it cannot be called representative of the progress of photography, which, after all, is supposed to be one of the uses of our Exhibition. "Sir Oracle" would most cringingly dare, "with bated breath and whispering humbleness," to suggest that we may have too much of a good thing.

Mr. Bird appears to "lay the flattering unction to his soul" that the country members are all thoroughly satisfied with the working of the Society. I greatly fear he is mistaken.—I am, yours, &c.,

ANDREW PRINGLE.

To the Editors.

GENTLEMEN,—I have to thank Mr. W. S. Bird for the expression of his good opinion of me, which I trust I shall continue to deserve. In replying to his letter, and in an endeavour to be brief, I will not attempt to deal with all his arguments and statements, though I regret that this opportunity is not afforded me. In the first place, where does Mr. Bird find in my letter that I express any dissatisfaction at the average attendance at the Council meetings? I complained that certain members, in their third year of office, utterly neglected their duties, admitting, at the same time, that this might have occurred through no fault of their own. I found a further excuse for these gentlemen in the fact that their being placed in this position might be the consequence of the operation of an absurd rule which saddled them with a responsibility which was unnecessarily made to last for three years. Mr. Bird accuses me of not having advanced any arguments against this rule. I advanced two very cogent ones; firstly, its unfairness to the members of Council themselves, and secondly, that it prevented that healthy interest which would attach to a general election, with the results which I went on to show; but this, the most important part of my letter, Mr. Bird does not seriously attempt to tackle. On the other side, what has Mr. Bird to say? He brings forward the one possible argument, that the retirement of one-third only of the Council maintains continuity of management, &c. This I expected, and was prepared to reply to, but I am saved the necessity, for Mr. Bird devotes the rest of his paragraph to demonstrating, with irresistible logic and force, the absolute impossibility of forming a Council which does not contain a large proportion, at least, of the present names. So certain is he that, under any circumstances, this "continuity of management" would be preserved, that he challenges me to *prove the contrary*. It is by using inconsequent arguments and raising feeble objections such as Mr. Bird's when wholesome reforms are suggested, that *thinking* people are impressed with a "sense of fatuous obstinacy indulged in at headquarters." The paragraph, as a whole, is unworthy of Mr. Bird's well known ability; to use his own words again, there is "sound only in it, not sense."

Passing over Mr. Bird's next paragraph with the remark that the theory is pretty, but it is theory only, I come to the subject of the meetings, and here, I am happy to find, we are substantially agreed. Mr. Bird is, however, misinformed upon one point. New subjects are rarely started at Pall Mall, but have usually been "sufficiently discussed" at other Societies before they drift there. I am said to be wanting fuller information. I am, at any rate, possessed of one piece of information which fills me with sorrow, and which Mr. Bird and his colleagues would do well to verify, and then to deliberate upon. It is that the Society, its doings and its journal, are rarely spoken of outside its own doors except with undisguised contempt.—I am, yours, &c., A COUNTRY MEMBER.

January 31, 1887.

[The whole matter connected with the Society having now been thoroughly ventilated, we here close the discussion.—Eos.]

Answers to Correspondents.

JOS. MILLER.—Dilute ordinary gas tars with benzole.

MEDIUM.—Try Canada balsam thinned with turpentine.

H. B. WALLASTON.—With you we agree that enough has been said on the subject. From an append to one of the letters you will see the matter is now closed.

J. E. GOWER asks if dextrine is a reliable mountant.—We have had very little experience with dextrine as a photographic mountant, as we ourselves much prefer starch for the purpose.

R. FURMAN.—The markings on the collodion transfers are due to their being made on dirty glass. Gelatino-bromide paper is quite as easy, indeed easier, to work than collodion transfers, while the results are, as a rule, far superior.

PRESS.—We know nothing of the press mentioned. For collotype printing in this country ordinary typographic or lithographic presses are usually employed. If the former, they must be of the best make, otherwise there will be a danger of the glass plates being broken by unequal pressure.

S. W. asks how two prints from a quarter-plate negative can be mounted so that they look stereoscopic in the stereoscope?—There is no method of mounting two prints from the same negative so that they show stereoscopically. We refer our correspondent to the articles on the stereoscope in the ALMANAC; he will there see the reason why.

ADA.—Take the advice given you, and do not expend any money, however small a sum, to be taught that system of colouring with a view to earning a livelihood. No photographer would ever give you employment, notwithstanding the plausible tale you have been told. If you wish to become a photographic colourist you must learn to colour in an artistic manner.

A. B. Z. inquires how "chromotypes" which are mounted as enamelled prints are to be spotted, as they, he says, must be spotted after they are removed from the glass.—Chromotypes with the enamel surface cannot be spotted after they are taken off the glass. They must be done while they are still on the plate and before the transfer paper is applied; that is, spotted on the back of the carbon image. This should be done with oil colour—that sold in tubes by the artist colourmen—thinned with turpentine.

H. STANTON says: "I have recently purchased a portrait lens by Shepherd at a sale, and upon trying it I could not get anything like sharpness. On taking it to pieces I find that it has only one back lens—a double convex; ought it not to have two? Pardon my ignorance, as I am only a beginner."—The lens is incomplete, as one of the components of the back combination is missing. If our correspondent discards the back lens altogether and screws the front one in its place he will then have a very useful single lens if it is stopped down to about one-fifteenth or one-twentieth of its focal length.

A. G. CLEMENTS.—1. If the enlargements are well made they will be nearly or quite as good as if the pictures were taken direct.—2. A whole-plate lens of the rapid type you would find very useful.—3. On the whole, perhaps, you would find a shutter working either in front or between the lenses more convenient than one working at the back for instantaneous exposures. If you adopt a drop shutter, that figured in the diagram will give the more equal illumination all over the plate.—4. Your failure in producing distance was not due to the form of lens used but probably to the state of the atmosphere or some other cause.

A. E. FOX asks: "What are the best materials for making a mixture suitable for producing a powerful artificial light for photographic purposes? Some years since I think you published a formula for such a compound in one of THE BRITISH JOURNAL PHOTOGRAPHIC ALMANACS, but I cannot find it. Can you kindly tell me where the mixture can be had ready for use?"—Any of the usual white fires employed in pyrotechny will answer. Here is a good formula:—Charcoal, two parts; sulphur, twenty-two; nitre, seventy-six. Another is, Nitre, sixty parts; sulphur, twenty; black antimony, ten; meal powder, six; powdered camphor, four. The composition may be purchased ready for use from any of the firework manufacturers.

C. RICHARDS says: "Will you kindly inform me how methylated spirit, which has been used for precipitating gelatine emulsion (ammonia process) can be purified to render it perfectly safe to use again for precipitating. My idea would be to filter to remove insoluble matter, then add, say, four ounces carbonate of potash to get rid of some surplus water as well as some of the salts soluble in the spirit, and afterwards distilling. Would the spirit after this treatment be as pure as it was before it was used? I find that even after the addition of potash carbonate the spirit retains a large quantity of, probably, nitrate of ammonia, clogging the wick of a spirit lamp in a very short time."—In reply: If the spirit be distilled as proposed, it will be ready for use again. A small proportion of ammonia may possibly come over, but it will do no harm.

NEMO.—1. See article on the subject of pedestal portraits, by Mr. W. M. Ashman, on page 100 of the ALMANAC.—2. There must, we surmise, be something unsuitable in the colours you employ. Procure fresh colours from another source.

THE LIVERPOOL UNPLEASANTNESS.—We have received a large mass of correspondence relative to the unfortunate cloud which has seemingly been damping the geniality that usually prevails among the members of the Liverpool Amateur Photographic Association. The correspondence arises out of the publication of a report of proceedings which—the Secretary being, as we understood, absent on the Continent—was furnished to us by a member with whose name we had long been familiar. Some members say the report is quite accurate, others aver the contrary. To publish the whole correspondence would necessitate our issuing a four-page supplement. We, therefore, must confine ourselves to a very brief synopsis, and in this take cognisance of only three letters. Mr. John H. Day says that the report in question was as untruthful as it was unofficial. The letter of Mr. Ellerbeck, he says, written apparently while he felt excited, really, although doubtless unintentionally, stated the facts incorrectly. The alleged grievances of which Mr. Ellerbeck complains have no real existence, at any rate not to the extent imagined by that gentleman. Mr. Adolph W. Beer replies to the statements of Mr. Ellerbeck *seriatim*. He says that the resignation of Mr. Ellerbeck, offered three years ago under very dissimilar circumstances from those which now obtain, the Council did not see any necessity then to accept; *they did not*, nor could they, bind their successors in any way whatever. "But the point," says Mr. Beer, "that affects me personally, and has been, by the evident intention of the writer, given the prominence of a foot-note, I must ask your indulgence to go into more fully. At the Council meeting of the London and Provincial Photographic Association, held preparatory to the General Meeting in November last, Mr. Ellerbeck laid down the astounding dictum that membership in another Society was a sort of disqualification for office in this! Mr. Ellerbeck knows perfectly well, but is not sufficiently candid to mention it, that he himself had as much to do with founding the bright, lively, sociable, little Society at Birkenhead, as I had—we being both present at the inaugural meeting and promising it support—and, as a matter of fact, Mr. Ellerbeck was a member until the first day of January, 1887. Some of us are sufficiently ardent amateur photographers to desire more opportunity for meeting than one and a half hours once a month, and with the two Societies we have the grand total of two one and a half hours, or three hours *per month* for photographic intercourse." Mr. Beer concludes: "Finally, no charge of the nature mentioned by Mr. Ellerbeck was ever brought against him by any one. The fact is, as is well known to every member of the Council, the whole of the circumstances leading up to this affair cannot be discussed in the columns of a public journal." Mr. Ellerbeck reasserts his former position, and enforces it in some detail. In the course of his letter, he says Mr. Atkins insinuates that he (Mr. Ellerbeck) sent us the report of the meeting of the 9th December. From a perusal of Mr. Atkins' communication we do not think this can be deduced; at any rate, it is *not* the case—our source of supply was different. Referring to Mr. Atkins' statement that no charges have been brought against him in our JOURNAL, he says that the charges were made behind his back. We are bound to say, and we do it with pleasure, that a very kindly feeling towards Mr. Ellerbeck has been expressed throughout all the numerous letters concerning this matter which we have received from Liverpool, and all join in expressing their sense of the service he has rendered photography there. Would it not now be well that the hatchet should be buried, and the pipe of peace be smoked? Before closing, we might throw out to our Liverpool friends a query as to whether it would not be better to do as the late North London Amateur Society, namely, throw the Society open to professionals as well as amateurs.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, February 9, 1887, will be on *The Artistic Treatment of Photographs*. Mr. Norman Macbeth, R.A., will demonstrate.

A CERTAIN photographer, not a thousand miles from Market Rasen, begs (we quote from his circular) "to inform the public that he has removed from where he did live, *but not from where he lives now*." We should think not.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The annual meeting of this Society will take place of Tuesday next, February 8, at eight p.m., at the Gallery, 5A, Pall Mall East, when the Report of the Council will be read, the financial statement made, and the election of officers take place, after which Mr. J. B. Spurge will read a paper on *A Method of Estimating Photographic Deposits, with Reference to the Printing Quality of Negatives*.

PHOTOGRAPHY IN COLOURS ONCE MORE.—The heathen Chinee has got ahead of the Western barbarian in a department of science which he had thought peculiarly his own. An American paper announces that a Chinese gentleman has discovered the secret of photography in natural colours—the realisation of the dreams of all our photographers from Daguerre's day down to our own. The inventor's name is a caution to the registrar of patents, and deserves to be set to music. It is Azurizawa Ryochi Nichome Sanjukanboz Kiobashi-ku. It is to be hoped that the process is a trifle simpler than the name of the discoverer. He is exhibiting the picture of the island of Enosbima, with the sand, sky, cliffs, trees, and native houses, all in their exact colours, and the effect is said to be singularly beautiful and surprising.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1397. VOL. XXXIV.—FEBRUARY 11, 1887.

COAL-TAR COLOURS IN PHOTOGRAPHY.

WE have, in our former article upon this subject, spoken in a general way of the wonderful series of colours obtained by treating in various manners some of the products of coal tar, so that we may now more particularly refer to the colour, or class of colours, at present exciting so much photographic interest—the eosines. The basis of all the colours embraced by this term is fluorescëin, a substance exhibiting when dissolved the property of fluorescence in the highest degree. This latter body again is obtained from phthalic acid and resorcin, so that the subject we are now treating of may be classed as either a benzene or a naphthalene derivative, or even a phenol, as resorcin may be termed a phenol. Thus much by way of classification as described in our former article.

Fluorescëin, then, is made by heating together phthalic anhydride and resorcin, the product being the substance in question in a crude state, but from which the various eosines may be prepared. In the pure form it is a deep orange crystalline powder, only slightly soluble in cold water, but easily so when a little caustic alkali is added. It then forms a liquid which is of a deep yellow colour when observed by transmitted light, but which appears a beautiful light green by reflected light, a green of such intensity that the liquid looks almost as though some opaque pigment were contained in the bottle. So intense is this curious effect that a single grain weight of fluorescëin is capable of rendering fluorescent thirty gallons of water.

The eosines come into trade in many forms and under many names, but all are fluorescëin compounds of one sort or another—nitro or halogen derivatives. They are various shades of red, and are described as blue shade, yellow shade, &c., or else have special trade names given to them. Most of them exhibit an intense fluorescence when dissolved, and usually in the highest degree when the solvent is alcohol. Tetrabromfluorescëin has often been named of late in the discussions upon orthochromatic plates, and its alkaline salts form eosines, which in the market are termed eosine J, eosine yellow shade, or soluble eosine. They are very readily soluble in water, but only slightly in anhydrous alcohol. Tetrabromfluorescëin itself is a fairly strong acid, and combines with metallic oxides, silver for example, so that the compound thrown down from this eosine by nitrate of silver is a true silver salt of definite and known composition.

When for the bromine of this compound iodine is substituted, we have tetraiodfluorescëin, the alkaline salts of which have a bluer shade, and are known under many names—eosine B, pyrosin B, soluble primrose, &c. The salt recently alluded to by Mr. Wellington under the name of erythrosine is

an alkaline salt of tetraiodfluorescëin. The aqueous solutions of the base do not exhibit any fluorescence. We also have aureosin J, eosine B N or saffrosin, lutécienne, rubeosin, in which chlorine or nitric acid take part in producing a change in the complex body.

We next come to the variety of eosines known as “spirit-soluble” eosines. They are obtained from the ethers of fluorescëin, and their potassium salts are sold as eosine soluble in spirit, ethyl eosine, methyl eosine, spirit primrose, &c. As their names imply, they are soluble in spirit, though only when containing a certain amount of water, as in anhydrous spirit they are insoluble, and but slightly soluble in water. Their fluorescence is very marked. We have also rose Bengale, phloxine, cyanosine—all eosines.

These spirit-soluble eosines have the brightest tints, but they are the most expensive to purchase, and in consequence are little used for dyeing purposes. Whether they are not better for orthochromatic plate production is a question, seeing that their fluorescence is greater in spiritous than in aqueous solution. We may here mention as a kind of warning that many coal-tar colours sold under particular names, and possessing fluorescent properties in solution, must not be lightly assumed to be compounds of a nature different from the eosines, and so able to be used if the existence of a patent rendered the use of eosine illegal, for there are many compounds known in trade under fancy names which are merely admixtures of one or another of the eosines with some other colour.

It may be interesting to note a few of the prominent reactions of the eosines, the striking nature of some of them rendering the detection of these compounds in solution not very difficult.

First, of course, comes their fluorescence, which is strongest when they are dissolved in spirit, brightest when the “spirit-soluble” preparations are used; but it must be remembered that the eosine B does not fluoresce at all when dissolved in water, and does so but little when in spirit.

Hydrochloric acid throws down a fluorescëin in a free state, and in various colours, according to the salt decomposed. Nitrate of silver and other metallic salts throw down coloured precipitates, and bleaching powder decolourises the solutions. The particular eosine acted upon may often be found by noting the colour effect produced by adding ammonia to the product of solutions decomposed by boiling with ammonia and zinc powder, and the precipitate dissolved in hydrochloric acid.

To test for eosine, the substance dyed with it is treated with warm water and a little ammonia, which will usually remove some of the colouring matter. Alcohol may also be

used, in case a spirit-soluble eosine had been used. The treatment of this aqueous extract, so to speak, with a strong solution of potash gives, according to the eosine employed, various colours, mostly of a red hue in the cold, changing to bluer or olive-green shades upon boiling. Spirit-soluble eosines are insoluble in cold strong solution of potash, but change in boiling from orange-red through violet to blue. Hydrochloric acid or acidulated chlorido of tin decolourise or turn the eosine yellow.

In a short article like this we cannot pretend to give more than the briefest outline of the properties and production of these interesting bodies, but our purpose will have been answered in showing what eosines are and in indicating their sources, and, finally, in pointing out what a very wide field is covered by the term eosine. It is no part of our purpose here to dissect the patent under which is claimed the sole right to use the eosines with gelatine plates; we can only trust that no clauses it contains will be operative in stifling experiments or placing obstacles in the way of progress in a direction in which there have already been obtained such marvellous results.

THE CAMERA CLUB CONFERENCE.

THE Conference which was held at the Society of Arts on Tuesday may be looked upon as having been a decided success.

The morning meeting lasted from eleven to one, and that of the afternoon from three till after five o'clock. The attendance at both *séances* was all that could have been desired. Captain Abney presided on both occasions.

In the morning, papers were read by Messrs. W. Adcock (*On Studies*), W. K. Burton (*On Testing the Sensitiveness of Plates*), and J. Traill Taylor (*On Amateur Enlarging on a Small Scale*). Those in the afternoon were *The Sulphuration of Platinotype Prints*, by H. H. O'Farrell; *Orthochromatic Photography*, by W. Hyslop; a paper on the same subject by Captain Abney; and *Rational Development*, by A. Pringle. Discussions followed the reading of each paper. The attendance was not confined to members of the Club, as there were several amateur and professional photographers unconnected with it present throughout the entire proceedings.

Meetings of this nature cannot fail of being attended with beneficial results, and we echo the hope expressed by the Chairman, that the Conference which would be held about the same time next year would be even still more successful. The papers read will, with one exception, be found on another page.

THE method of transferring negatives, taken on paper, to films, recently introduced by the Eastman Company, and described in our last issue, promises to prove very useful in the production of reversed, or inverted, negatives for collotype and other photo-mechanical processes, where a reversed image is an essential, also for single transfer carbon printing. Of course all paper and film negatives may be printed from either side, but when the printing is conducted through the support, whatever it may be, there will always be to a certain degree a loss of sharpness. It need not be much, it is true, if direct light be used, yet still there is some, and, what is more, if the medium which supports the image contains any granularity, the grain must, more or less, be manifest in the resulting impression. Here is how the new process may be utilised. Instead of treating the glass with French chalk, as described last week, it is simply cleaned, and afterwards coated with the collodion. Then, when the image is transferred, all that is necessary is to dry and varnish it, and the thing is complete. By this means we obtain a reversed negative on glass, which, as a

matter of course, will print quite as sharp as if it were taken direct upon it in the first instance, while it will be perfectly free from granularity.

COLLOTYPE printing appears to be coming more and more to the front in this country, though, it must be confessed, it is as yet not nearly so extensively worked here as on the Continent—Germany, for instance. Still, there has been a great increase during the past year or two in the numbers employing the process commercially. Collotype printing by machinery is now being practised by more than one firm in the Metropolis, and we are informed it is to be shortly introduced in the provinces, and very good work is being produced by this method of obtaining the impressions. It is generally admitted that, at the present time, machine printed collotypes are, in some respects, inferior to those produced by the most skilful workers with the hand press. When lithographic machines were first introduced it may be remembered that the same remark applied to them, but as we all know, some of the finest lithographic printing is now being executed by machinery.

PROBABLY improvements will be made in collotype machines which will, eventually, remove the reproach that now applies to them, the same as in the case of lithography. Unfortunately collotype, like lithographic machines, are somewhat expensive things, and this will doubtless prohibit their general adoption except in large establishments. A machine of medium size costs several hundreds of pounds. At present the manufacture of collotype machines (Schnellpressen) is confined, we understand, entirely to Germany, but there is little doubt, if a demand arises for them, but that they will eventually be forthcoming from English printing machine manufactories. In construction these machines do not differ materially from lithographic ones; indeed, the latter may be really converted into the former with a little ingenuity.

DURING last week there were several panics on the Stock Exchange, and many excited groups of brokers and jobbers were to be seen, all day long, in the neighbourhood of Throgmorton-street. Favoured by the bright weather, some very characteristic pictures, representing the commercial phases of City life, might easily have been secured with instantaneous exposures. During a commercial crisis excellent studies of character may often be obtained in the neighbourhood of the Exchange, or on the Liverpool flags. The Stock Exchange has always possessed, amongst its members, a large number of amateur photographers, but we can readily imagine that on occasions such as the above they are too much engrossed in their immediate business to give a thought to their favourite pastime, or the interesting pictures that they might obtain. Nevertheless the circumstance is worth mentioning.

Two or three cases under the Trade Marks Acts, of interest to those who supply photographic requirements and wish to distinguish their specialities by some particular or conspicuous title, has recently been decided in one of our law courts. From the reports it appears that an immense number of applications have been made to register the word "Jubilee," as applied to various manufactures, as a trade mark, one of these being a particular make of note paper. An action was instituted by one firm, who had registered the word, against another firm to restrain them from using the same term. The action was resisted on the ground that Jubilee was not a "fancy word" within the meaning of the Trade Marks Acts, and, in the result, the judge ruled that it was not. A similar decision was given a few days previously, in the case of the word "Electric," as applied to a fabric. We believe that any word, fancy or otherwise, may be registered as a trade mark, provided it be inserted in, or is accompanied by, some special or distinctive device. But then it can only be registered as a whole, and any one will still be at liberty to use the word by itself. This fact should be borne in mind by those who are seeking for distinctive names for their wares, whether they be instantaneous shutters, dry plates, or some modified process of producing pictures.

FROM a remark made by Captain Abney at the Conference on Tuesday, it is evident that he does not attach *very* great importance

to the value of isochromatic plates as applied to ordinary landscape purposes. If we understood him aright, he believes that their real use will lie in the copying of paintings. But, it may be queried, are not paintings transcripts of nature, not only as regards drawing, but also colour?

In a speech made at the last meeting of the London and Provincial Photographic Association, when platinum printing was very ably demonstrated by Mr. F. M. Edwards, who is a master of that special art, Mr. Willis very clearly showed the difference between the fading of a picture and the discolouration of the paper or other substance upon which that picture was impressed, a distinction sometimes apt to be lost sight of, as was the case several years ago, when the subject of the alleged fading of carbon prints was prominently brought before the public in these pages. The fact, however, was clearly shown then that whereas a certain sample of paper then in use was liable to, and did, become discoloured, the image itself remained unaltered. This has a bearing on the discussion on platinotype that has for some time been going on. The image itself, and the basis on which it is supported, are two different things.

ON THINGS IN GENERAL.

PRINGLE and Platinotype make such a pretty alliteration that I feel inclined to start at once upon a subject which, still holding the field as it does, is exciting a lively interest at the present time, and as the gentleman named is such a lively writer I feel sure we shall all be kept awake the next few weeks. Whether with the most engaging candour he was not, in his now celebrated article, taking quiet "pot-shots" at the integrity of the process I will not attempt to determine; but I do say that I look upon his contribution as an especially valuable one. He has shown that there is something in the whites of the platinum prints he examined that can be yellowed by sulphuretted hydrogen: *ergo*, let it be discovered what that something is, and how to prevent its presence, for it is obvious that if it make its appearance in one man's prints it may also do so in another's. The poor albumenised paper print decidedly goes to the wall in the discussion; but it still holds its own with the public, and is likely to do, I imagine, at least in the case of small work, for none of its rivals can there surpass it, and as to permanency, the permanency of a properly executed print on silvered albumenised paper is simply a question of keeping. Any photographer of experience knows where to lay his hand upon dozens of prints, twenty or thirty years old, as good as in the day they were produced. It is all very well to talk about the sulphuretted hydrogen in the atmosphere—we know it is there in plenty; but I am making a great mistake if it be not sulphuric acid that we are to look to for an explanation of faded albumenised prints.

What negatives one used to produce when dry plates and re-touching were not! Mr. F. M. Edwards strikes a chord which will cause a sympathetic vibration in the bosom of many an old stager, when he says, as he did at the meeting of the London and Provincial Photographic Association, "the negatives turned out nowadays were not worth calling negatives at all." Bravo, Mr. F. M. E., for speaking out your mind! I think a great many more will echo your sentiments in a few years time, when albumenised prints from these negatives, so dim and poor to the eye, shall have run their course, and shown how albumenised prints can be produced so as almost to be warranted to fade.

The meeting for the month, however, which for exciting interest must carry off the palm, was the Parent Society's, on the twenty-fifth ultimo. It was rather hard lines for Mr. Dixon, after having worked up a process for making a successful orthochromatic plate, to feel that his labour was thrown away. His throwing up the sponge as he then did was to my mind absolutely pathetic. But he acted as a wise man. If he were to fight the patent and win it would only be for others as well as himself. After he had borne all the expense others would step in and reap the profit. This, too, assuming he did win. I have in my journeying about the world met confiding individuals who are under the impression that when a man wins a lawsuit the other side pays all the costs. What would I not give for such trusting faith! One of the most costly of modern patent trials connected with chemistry was in connection with the very subject of

the coal-tar dyes, and solely turned on the meaning of the word "dry." By-the-by, let me suggest to Messieurs the Editors that they give a reprint of the celebrated eosine and gelatino-bromide patent; it would at the present time be of great interest. Looking at the various discussions upon this wonderful eosine subject, it seems to me to be generally assumed that the eosines are all fluorescent. Such is not the case, whatever bearing the fact may have on the matter.

I was pleased to see an article from the pen of Mr. Lewis Wright illuminating these pages, for whatever he writes is always to the point, and, what is more, thoroughly practical. Some of his experience in optical and lantern matters, if placed at the disposal of the readers of THE BRITISH JOURNAL OF PHOTOGRAPHY, will be a valuable addition to the ever increasing usefulness of its pages. It will be long before oxygen is displaced for optical lantern work for large exhibition rooms, though, with Mr. G. Smith, I must confess to a partiality for a good paraffine lamp as an illuminant, and the old two-wick Sciopticon takes a deal of beating. True, the bare white disc will show a faint upright bar, but it is quite invisible when a picture is thrown on the screen.

That was a good idea that was put into execution at the Birkenhead Society's lantern exhibition. The room did not allow the usual sheet being put up, so Mr. Evans provided "a piece of drawing paper about six feet by eight feet square" (whatever that may mean), "such as is used by architects, and can be bought up to any length." I have not ever come across any such paper so wide as six feet, though when mounted on cloth it can of course be made, by joining, of any width, until the limit of the linen is reached. It occurs to me that, as the lantern must have been at the same side of the screen as the audience, it (the latter) must have been an uncommonly small one. There are many varieties of screens, not often mentioned, that can be used for lanterns with great advantage. I have seen tracing cloth used with excellent effect, but the greatest width it is obtainable in is only a few inches over a yard. The other day I saw the wall of a lecture-room itself prepared for the purpose. Instead of whitewash or distemper, the last coating was of Parian cement, which gave a capital surface and could be cleaned whenever required, and thus the mess and nuisance of the painter and his myrmidons avoided.

Speaking of the projection of an image on a screen, calls to my mind an article from an American source which in the first number of this JOURNAL for the year was given a prominent position. The writer, Mr. Walmsley, says: "It is highly desirable that the rays of light, after passing through the objective, should be allowed to diverge as speedily as possible. Where they are confined to the limits of a long tube of small diameter, it will be found that only a small circle of light will be thrown on the ground-glass when the camera is closed up short, and that it must be lengthened to a considerable extent before the entire plate is illuminated." After writing a practical article, one can scarcely understand such meaningless matter as this. An ordinary microscope tube will show on the ground-glass as much as is desirable, on the grounds of definition, and the only way the entire plate is illuminated is by increasing the size of the image. It would have been more to the point if he had pointed out the usual failure of beginners with photo-micrography, and that is the ring of light, something like the old "flare spot," always produced unless the microscope tube be lined with black velvet or something subserving a similar purpose.

FREE LANCE.

NOTE ON CASTING IN PLASTER FROM PHOTOGRAPHIC CLICHÉS.

[A Communication to the Edinburgh Geological Society.]

It is sometimes desirable to convert a photograph (say of certain of the *Microzoa*) into a plaque, which can be mounted on a tablet and exhibited in a case. This can be done by taking plaster casts from reliefs in gelatine. They are producible in two ways. 1. On the commercial dry plate; 2. On *clichés* of bichromated gelatine.

1. On the commercial dry plate. I have experimented with a few makes, but find the gelatine too soft in most cases. One make (possibly containing bichromate) gives tolerably good results, but different batches differ in their power of resisting the rather severe treatment to which they are subjected. The treatment is quite simple, and consists of dipping the plate (it must not be alumed) for a few moments in water, kept at a uniform heat of 90° Fahr. by an automatic gas regulator. I should think that a plate could be put on

the market suited to this particular purpose, and its utility in the various photo-mechanical printing processes would ensure a steady demand for it.

Whilst the relief is still moist and at its best, pour on No. 1 plaster, as in ordinary plaster casting, mixed with a little alum to harden it. When dry the plaster leaves the gelatine without much trouble, no lubricator being needed. The resulting cast may of course be coloured if desired.

2. On bichromated gelatine. This method is well known. It has the great advantage of being capable of giving a higher relief if required according to the thickness of the gelatine. On a moderately hard gelatine hot water may be used, a fact known almost as long as photography. A little caution must be exercised in the choice of a subject. Their microscopied sections are for obvious reasons unsuitable where strict accuracy is required; but when the lights and darks of the *clichés* (upon which intaglio and relief depend) nearly correspond to the real intaglio and relief of the object photographed, the resulting cast will of course be accurate as well as beautiful.

THOMAS STOCK.

PHOTOGRAPHIC LENSES.*

The Optical and Focal Centre.—It is in many instances desirable that one should be able to know where the optical centre of a lens is situated. It is a property of this centre that any ray, refracted by the lens, which passes through it emerges in a direction parallel to its incidence. It is from a point near to, although not quite at, the optical centre of a lens, or combination of lenses, that the focus must be measured. To find this centre, draw two parallel radial lines, one from the centre of each curvature, and both being oblique to the axis; then connect the points at which they touch the curved surface by a line, which, in the case of a meniscus, must be prolonged till it meet the axis. The point at which this junction line touches the axis is the optical centre. In class-books on optics the following rule is given: "Multiply the thickness of the lens by the radius of one surface, and divide the product by the sum of the radii, and the quotient is the distance of the centre from the vertex of that surface."

In a combination of lenses there is no fixed point which can be termed the optical centre. The mistake is frequently made of assigning it to a position near the diaphragm which has not necessarily any relation to that of the centre, which can only have its position determined upon knowing the precise circumstances under which the combination is to be used, for it has strict relation to the conjugate foci. What is commonly termed the optical centre in a combination is in reality the centre of conjugate foci, and this is determined by the conjugates, which may change with nearly every change of picture taken.

The *equivalent focus* of a lens is so termed from an image formed by it equalling in dimensions that made by a single lens. It has no relation to the misleading term "back focus" so frequently employed. It is not difficult to conceive of an objective, the back focus of which—that is, the distance between the posterior surface and the ground-glass of the camera—may be four inches, while the real or equivalent focus is eight inches. As it is of great importance that photographers know precisely the foci of their lenses, I shall describe methods by which this may be ascertained. Let me first of all observe that, although it has been taught by some that the focus must be measured from the optical centre, this is not quite correct. In every lens or combination there are two nodal points, which are centres of admission and emission. They are sometimes designated the Gauss points, from the fact of Gauss having communicated an investigation of their properties to the Royal Society of Göttingen in 1840. In the case of a simple biconvex lens these points are situated between the optical centre and the surface, while in a meniscus lens it is outside of the lens and a little within the optical centre. It is the back nodal point which concerns us at present, as that is the one from which the focus is measured. In a rectilinear combination this posterior focal centre is situated between the diaphragm and the back lens. Opticians interested in this are referred to Secretan's treatise on the true point from which the focus should be measured, or to Gauss's memoir.

It has often been recommended to determine the true focus of a lens of this nature by focussing the camera upon an object, so that the image and the object shall be of precisely the same size, and divide the distance apart of the two by four, the quotient expressing the true equivalent focus of the lens. This is altogether misleading as applied to the combination lens in common use, the focus thus obtained being greater than the true focus by nearly one-fourth of the distance at which the lenses are separated in the mount.

Out of several methods by which the equivalent focus may be

* Continued from page 73.

ascertained, I shall mention only a few. Select a very thin spectacle glass which, after trial, is found to give an image on the focussing screen of the same dimensions as that given by the photographic objective; and the distance of that glass from the focussing screen, less one-fourth its thickness, is the focus. Or, having marked upon the ground-glass the precise spots upon which two well-defined objects depict their images near the margin on opposite sides of the screen, unscrew the lenses from the mount and insert a pinhole diaphragm made in a thin metal plate. Rack the camera in or out until the images made by the pinhole correspond with that of the lens in dimensions. As before, the distance between the ground-glass and diaphragm is the focus.

The way which I prefer is Grubb's, on account of the ease with which it may be carried into operation and the accuracy of the result. On the ground-glass of the camera make two pencil marks at either side, each being a distance of an inch or so from the margin, although this is not material provided both are alike as regards distance. Having brought up a table to the window, spread upon it a sheet of paper, and upon this place the camera. Focus upon a distant scene, and rotate the camera until a well-marked object in the scene—such as a chimney or spire—is superposed on one of the lines drawn on the ground-glass. Now using the side of the camera as a ruler, draw a pencil line upon the sheet of paper upon which the camera is placed, and rotate the camera so as to superpose the same object upon the other mark on the ground-glass, and again draw a line upon the paper. Having removed the camera, for which there is no more use, continue by aid of a flat rule these two angular lines until they meet at a point, then connect them by a line as in the capital letter A, which line must equal in length the distance between the two marks made on the ground-glass, and with a foot-rule measure the junction of the angular lines to the centre of the cross line, and you have the true focus of the lens.

Schroeder's method is also simple and excellent, although it implies the possession of a camera capable of extending to about twice the focus of the lens. Extend the camera until the dimensions of the image on the ground-glass and of the object in front are alike. Having marked the position of the camera back in relation to its baseboard, slide or rack it in until a distant object is in focus, and again mark the position of the back. The distance between the two positions, or that through which the camera back was made to travel from the first focussing to the second, gives the equivalent focus of the lens. In a rectilinear symmetrical doublet of wide-angular aperture which I possess, having an equivalent focus of $13\frac{1}{4}$ inches, a reputed focus of 13 inches, and a back focus of $10\frac{3}{4}$ inches, I find that the focal or posterior nodal point is situated '3 inch back of the mechanical centre of the lens. This is a matter that greatly concerns those who have to make copies to scale, and who have the sides of their cameras graduated in order to facilitate accuracy and speed.

(To be continued.) J. TRAILL TAYLOR.

BEAUTY OF POSE, PROPORTION, AND FEATURE IN PORTRAITURE.*

AFTER the curve of the principal line has been determined—by means of the disposition of the arms, hands, &c.—it remains for the artist to decide whether he will keep his composition simple, or enrich it with a secondary line, subordinately repeating the first in some region further removed from the centre. If the design is to be enriched, then, "though to a principal group a second or third be added, and a second and third mass of light, care must be taken that these subordinate actions and lights, neither each in particular, nor all together, come into any degree of competition with the principal; they should merely make a part of that whole which would be imperfect without them." To suit my present purpose, I would read "leading lines" for "groups," and "contrasts" or "lines of position" for "lights." And, where such embellishment is undertaken, the utmost care must be observed that the minor details of the subordinate schemes do not clash with those of the first. The principal line of direction should originate not too far from the centre, sweep in a "fine" curve towards the margin of the enclosing form, and return to itself at some little distance from the point at which it commenced. The chief point of interest, as I have said before, may be situate anywhere in this line, which should never be allowed to get out of the picture, nor even to touch its margin at any point. In a full-length portrait the body and arms will form the thickest part of the line, and no secondary curve of direction must cross the first at right angles, even when comparatively subdued in emphasis of light and shade; and in this case also it must not be allowed to run parallel

* Concluded from page 54.

with the principal line. Minor lines of direction may cross and coquette with the leading line as much as they like, but in no wise must they interfere to prevent its asserting itself as the subject of the picture.

Thus we see how pose is determined by the first requirements of good composition. But, having roughly estimated the relative positions of our principal points of attraction with regard to our boundary lines, and decided as to their relative values of light and shade with regard to each other, there still remains for us finally to determine the position and aspect of the details, regulated so far by what we have already done, but which have to be modified more or less—but generally more—by the incapacities or imperfections of our subjects. This involves a partial rearrangement of almost everything; and depending, as I have said, on the individuality of our models, cannot at any length be touched upon in this paper.

Study the human figure. Avoid overcrowding and false accentuation as much as flat surfaces and empty uninteresting spaces. Mark, above all, the requisite unsymmetrical balance of the human form. See how one line of position alternates with two lines of direction, and *vice versa*. Note the excessive difficulty in ever getting two parts, which in nature are the same, to assert themselves with equal force at once. Look at the utter absence of sharp angles, of right angles, of straight lines, and of perfect circles in nature. Since the forehead surrounds the eyes, the cheeks, the nose, the jaw, the mouth, and so on, I infer that a comparatively clear expanse should be allowed near every point of interest. This expanse may indeed be without limit if the point of interest is to be looked upon as an isolated fact, and, together with the absence of angles between the subject and the bounding lines which such a treatment implies, affords the best explanation of the exceptional beauty of a picture whose subject is entirely within the canvas, and also of a vignette which imperceptibly fades into nothing. On the other hand, this expanse must be carefully limited where the subject is to be considered as a compound one, as in the case of a historical picture containing many figures, or a portrait embracing a head and two hands, where each point of interest forms a line of position having a very intimate relationship to the others, when too much consideration cannot be given to the lines of direction which bind them to each other, and determine the beauty of the curve which I have called the principal or leading line of the entire picture. For this reason it is that we insist that the dress must be intermediate in tint between the brilliance of the high lights of the face and the shadow of the background; or, as in the case of a vignette, be intermediate in contrast as compared to that of the head, for it is by such treatment alone that we can ensure a broad, swinging, leading line to the entire composition. It is for this reason, too, that we do not allow any point or line of importance to impinge upon any bounding line, and thereby to add a false quantity to the concrete design, nor permit of the exit of any leading line of direction at a right angle to any of the lines enclosing our subject, unless we cannot possibly help it, as is the case where we have a three-quarter length figure of a man standing. This it is that determines that a mountain shall not be cut off either at its base or at its summit, and which suggests that a figure is better cut off in the middle of the chest, thigh, or leg, than at the chin, waist, knee, or toe. Lastly, it is this that forbids of an akimbo elbow to just touch a bounding line, thereby to form a K, and will not allow a pronounced line of direction to bolt out of the picture exactly at a corner, and thus to suggest a series of radiating lines, V—, foreign and antagonistic to the design.

The power justly to criticise a work of art, chiefly in its broader aspects, is, I think, as rare as it is important, else the scarcity of truly beautiful compositions would be less. Generally speaking, if a picture be not absolutely faulty, the absence of beauty in the composition is entirely overlooked, and the eye allows itself to be cajoled by mere beauty of detail. A better judgment insists, however, on first of all deriving pleasure from the entire effect, as composed of a mass of flowing curves, composed of masses of light and shade, existing utterly independently of their subject-matter. From this point of view, a very beautiful picture may be formed representing nothing at all, and which one man may imagine to be meant for one thing, and another for some thing entirely different. Everything to which I have referred hitherto can only appear as perfectly beautiful as possible where this is considered.

HUGH BRENNER.

THE PHOTOGRAPHIC CONFERENCE.

As announced on another page, a Photographic Conference, instituted by the Camera Club, although open to the public, was held on Tuesday in the Large Hall of the Society of Arts. We give below

the various papers, with one exception, which were read on the occasion.

MORNING SESSION. STUDIES.

By W. ADCOCK.

By the title I give to this short paper, I mean detached parts of pictures, as distinct from those composites which, when joined up and employed, we, in a certain sense—not its highest—call a picture. If in a landscape we take foreground, middle, and extreme distance, we get the elements necessary to a picture. If of these we take one section only, we should probably call it a view. Now, if out of the foreground we took a large thistle and produced it separately, we might, however pictorially it was treated, very properly consider it a study.

Similar ideas apply to figure. To get a picture we should look beyond a mere bald figure for accessories to give completion to it. In the production of a large and elaborate photograph we can easily see how necessary it would be to study every part separately. The pose of a model, the turn of a head, the exact expression, the disposal of the hands, the folds of drapery, the position of a chair—all would be worked out, not merely by thinking of, but by producing pictorially. In this photographers only follow in the wake of painters, who, fortunately for the world, give it their first and upward thinkings towards perfection, in the form of studies.

We know how a painter, when thinking of a great work, first makes studies of its parts, then of its components as a whole—often more than once—before he decides how he will treat his finished work. It had been so from the earliest days of art, and the studies of the old masters are amongst the treasures of the world. These are the histories of pictures, and show how first conceptions, crude by comparison, developed into those creations of genius which have delighted until now, and, while they last, will delight succeeding ages.

A distinguished living painter, a few years ago, took for the subject of his Academy picture that phase of French life we should call “washing clothes on the banks of a stream.” The scene was laid at Etaple, with the village in the distance. He made studies in strong, bold water colour, of each group or single figure for his picture, and then he grouped the whole into a sketch, which could be called a study sketch, or a sketch study, and from this he painted in oils his large work.

By purchase, this larger sketch, which received completion as a finished drawing after the Academy picture was painted, together with the preliminary studies, came into my hands, and are not the less prized by me from the greater fame every succeeding year brings to the artist.

It is, I take it, safe to predict that a great master in photography, before deciding upon such a work as *Dawn and Sunset*, and while the subject is incubating in his mind, would make many studies of its parts.

But I aim to-day at creating an interest in one special class of studies. If we go to the Kensington Museum, we find studies of hands—for instance—that, from the interest attaching to them, are almost priceless. Why is this? It is because of the marvellous beauty of their drawing. It is notorious that, to the incompetent artist, hands are more difficult to draw than faces, and it is common to find, in otherwise fine pictures, a shirking of the hands. They are often an indication of something left to the imagination to say what. In new pictures remonstrance with this defect is met by the remark, “Oh, do not detract from the power of the head by minor details!” This interpreted means, “We don’t profess to paint hands.” Yet hands give great scope to the master for brush-drawing. Reverting to Kensington Museum, I would ask what sum would purchase the studies of Mulready, mounted on a single revolving screen, to be found there? They are studies of this order—hands, feet, and detached limbs. Many of these probably were drawn on days too dull to paint in, or on winter evenings. Is there a hint here? Can we, by camera and lens, take hands or feet, enlarge them to life-size, and produce *perfect drawing*? Can we not produce every line of graceful beauty found in the hand of girlhood, the muscular vigour of manhood, and the loose, wrinkled skin of age, with a fidelity few capable draughtsmen would spend time in producing? Before we give a negative reply to this, I say, let us try.

Is another hint here? Would hands and feet, and eyes and ears, so produced, have value as copies in our schools, Board and otherwise, where drawing is now so largely taught? This seems to me a question for a professional. I hold up the hint in large letters. If worth anything, use it; if not, let it go.

Perfect drawing, to the trained eye, is ever a thing of beauty. With the lens, perfect drawing can be unquestionably obtained by taking small and enlarging.

What to-day would be the value of a photograph of the hand of Wellington, or, say, the sword-hand of Murat? If these things would be prized by a nation, will an exact portrayal of your hand be without interest to your grandchildren?

The power of enlarging given to amateurs by bromide paper is almost illimitable. I am only just beginning to find it out. For years I have been working directly, figure, unusually large in size. I like it still, but I am a convert to this, that he who will afford a large lens with advantage may; while he who will be content with a small rapid rectilinear (say eight-inch focus) may produce splendid work, both directly and by enlarging. And here, at the risk of telling those who know, I tell all who

do not, a lens that will take a plate sharp to the edges will enlarge *that plate* to any required extent. With the size I have named, I take $7\frac{1}{2} \times 5$, and enlarge up to 23×17 .

But of studies. Oh, amateurs, what a field you have! Of what *cannot* you make studies—I mean art studies, if you so treat them.

Besides the hands and feet I have specially referred to, what have you not in figure! An expressed thought—an idea—a sentiment—a passion—an act being done, all of these are open to you, with your own room, or, if you prefer it, with your back-yard as a studio and a blanket on a wall for a background. A turkey is a fine study; a brace of hares, a couple of rabbits, and a couple of ducks; a big thistle is splendid, big as a good-sized gooseberry-bush; take two, one growing and vigorous, the other withered and dying, both in bloom—mind that—and when taken and enlarged, look at the drawing of them. The foliage of a growing carrot is beautiful—try it; so is a spray of apple-tree in leaf and bloom.

Then of dogs! Oh, the long-haired little dogs, the Dandy Dinmont, and every variety of long-haired Scotch poodle. What a dog for a study is the colley!

I tell you the facility of enlarging gives you over all these things a power of making of them things of beauty. One advantage is they are at hand, and you have not to go ten or twenty miles to find them.

I forgot a cat. I will show you a cat. "A cat" would be your description of it—mine is "My cat." It is a distinction with a difference, which leads me to say your cat would be of more value to you than an unknown one. Colderoy paints cats; as Mark Twain would say, well, Colderoy does, but we cannot all afford to buy the delightful cats he does paint. Will those who cannot be content with one on bromide paper, as I am? It is a study I commend to your notice.

I will not weary you, but before my last word let me say there is nothing in the study which will bear careless manipulation. The diffused bluntness I have held permissible, if not advocated, in large direct work, will not serve in enlargements. A negative must be sharp all over, or those parts out of focus would, by enlargement, be terribly out of drawing; and what I am holding up for is *beauty* of drawing.

To the beginner, and to those who have a bad one, I say, Get a good lens. Do not expect, for thirty shillings, an instrument as good as, at some makers, you would pay five pounds for. Let me not be understood as advocating these studies to the exclusion of other and more extended work—to landscape, to seascape, to figure in every phase. What I say is, that in studies taken small and enlarged you have a class of work second to none in interest; work that, by the very care and thought you give it, will befit you for pursuing, with more intelligence than you would otherwise possess, every phase of picture of which photography is capable. Some of the studies I have suggested may be considered photography made easy. I may be asked what scope does a turkey or a brace of hares give for showing the art side? I reply, the lines, the lights, the shadows, may be harmonious and exhibit good taste from one arrangement, but obtrusive and exhibit bad taste in another. In naming some things here, I am, perhaps, thinking of the amateur newly fledged, and showing him how easily he can find a subject at his own door when he wants one.

I enlarge by daylight, and the cost of adapting a camera to the purpose did not exceed 3s. 6d. Nothing done to this camera prevents me using it for ordinary purposes.

I cannot forbear saying here that, apart from my advocacy of hands and feet as specially worthy every one's attention, it is to the studies attainable from the human figure generally I look for the greatest pleasure, the greatest instruction, and the easiest attainments. In coming into London a month ago, I saw a dozen good studies as I passed in a cab up a single street. If you care for landscape only, devote yourself to it. Ascertain what Millet, Corot, Leader, C. E. Johnson, and Willie Wyllie, have done in painting, and what Emerson, Bankart, Gale, and many others, are doing in photography. If you aim at attaining their height, go ahead, but spare your friends view-taking.

Do not think all required of a photographer is that when he goes for a holiday, he may take views of his playground. He should become an amateur that he may improve his taste, cultivate a love of the beautiful, distinguish it from the commonplace, and inoculate his children with the virus.

I think, to the amateur, there are some ruts in the photographic road. Keep in them if you like; I only point to them. A certain make of plate may be a rut; Beach's developer is a rut; photographic time-tables are an awfully deep rut; landscape only is a rut; and—yes, decidedly!—everlasting figure must be another.

My last words are, whatever you do—however much, however little—aim with all your energy at raising photography to an art by putting art into your own work. Without it the best *technique* is valueless.

TESTING THE SENSITIVENESS OF PLATES.

By W. K. BURTON.

THE term "testing the sensitiveness of plates" is one which should scarcely be used at all, for it involves the supposition that we have some standard or unit of sensitiveness wherewith we may measure, or in terms of which we may state, the sensitiveness of plates. Now we have no such standard, and, so far as I can see, are not likely to have one. For this reason the only thing that we can do is to *compare* the

sensitiveness of plates, and I shall presently show that even this is impossible with anything like accuracy. I shall, however, say a few words on the practical methods, whereby we may compare approximately.

First, we have sensitometers. The principle of these instruments is well enough known. They are—or would be, were they accurate—a means for measuring the smallest amount of light that is capable of producing any developable image on a plate, the assumption being that the sensitiveness of the plates is in the inverse ratio of this amount of light. Thus, for example, if it takes only a quarter the amount of light to produce a developable image in the case of plate A that it takes in the case of plate B, plate A is four times as rapid as plate B, and it is assumed that it will give a similar negative in a quarter the time. But for this assumption there are, I believe, really no grounds; at any rate, we certainly have no right to take it for granted. And as it happens, it is not correct, or is, at any rate, only correct to a very limited degree.

The very fact that a supplementary exposure has the effect of greatly decreasing the amount of light necessary to produce a developable image, whilst it scarcely appreciably increases the camera sensitiveness of a plate, shows that the rule does not of necessity hold good.

For example, if we have a plate which would require eight units of light to produce a developable image, and we give it six units by exposing it to diffused light, it will evidently require but two more units of light—received through the sensitometer screen—to produce a developable image; but the plate will certainly not be four times as quick after it has received the supplementary exposure as before.

Now, the question is, do we not have plates differing in their actual construction, somewhat as the plate we have imagined differed before and after it had received this supplementary exposure?—plates, that is to say, whose variation in sensitiveness is not in the inverse ratio of the quantity of light necessary to produce a developable image. I certainly believe that we have, and I think it is very easy to show this.

We take a plate of the very highest sensitiveness, such as shows 25° on Warnerke's sensitometer, and we take another plate, say, about ten times as slow. It may show anything from 8 to 13 or 14. We now expose the second plate for such a length of time that we get an impression of the figure 25 on it, and we compare the two images. We shall see a vast difference. The last row of five figures in the very rapid plate will be a mere shadow, and the second row will be but little better. In the case of the slow plate, which has had the very long exposure, figure 21 will probably show with a fair amount of distinctness, and in the second row from the end—figures 16 to 20—the density will rise very rapidly.

It will probably have taken from twenty to thirty times as long exposure to get out the figure 25 on the slow plate as on the quick plate, but if we give the two plates exposures in the camera, varying as 20 or 30 to 1, is it to be supposed that we shall get two similar negatives? We certainly shall not. If we have been, in both cases, on the under-exposed side, we shall find that we have, perhaps, exactly the same amount of shallow detail in both cases, but that great part of the detail which is thin and ghostly in the rapid plate is strong and vigorous in the others. Nor can we, by varying the exposures in any way we choose, get precisely similar negatives in the two plates. The curves of sensitiveness are not the same, and no possible exposures will give negatives precisely similar. All that we can do is to produce on each plate that somewhat indefinite article, a "properly exposed negative." We may give the slow plates such an exposure that, whilst we have the very deepest shadows rendered on clear glass, we have all the detail strong and vigorous. We shall, however, find this impossible with the rapid plate, for we must expose till the extreme shadows are considerably veiled before we get that vigour of shadow detail which will entitle the negative to be called "well exposed."

It is on account of the differing "curves of sensitiveness" that we cannot really even *compare* with accuracy the sensitiveness of different plates.

There are, however, methods whereby it is possible to perform this comparison with approximate accuracy. Indeed, the very fact that we are able to speak of one plate as four or eight times as rapid as another is proof of this. I believe, however, that the only method of comparison which deserves the name of even moderate accuracy is that of giving, with the two kinds of plates to be compared, such exposures in the camera that each will produce a "properly exposed" negative, and comparing the exposures required to produce this result. The subject should be one having a great range of tint—for example, a white statuette draped in black velvet. It is thus possible to judge of the plate, as regards its capacity for rendering a range of tone as well as its sensitiveness.

Even by the intelligent use of a sensitometer, it is possible to get a comparison of sensitiveness which, if not even as accurate as that got by making two camera exposures, may still be of some practical use.

As to the sensitometer to use, there can be no doubt that those sensitometers in which the light is measured by passing through apertures of varying size, are the most accurate; but Warnerke's sensitometer has come so much more than any other into general use, that when a reference to "the sensitometer" is made, it is understood to refer to Warnerke's instrument. His sensitometer, as every one knows, consists essentially of a screen divided into twenty-five squares, each of which has a transparent film on it, which obstructs more or less of the light. The squares are numbered from 1 to 25, 1 being the most transparent. The instrument, apart from the subject of the light, to be mentioned hereafter, has several drawbacks. Thus, the opacity of squares bearing the

same number is by no means precisely the same in all screens that have been sent out. Again, in any one screen, the difference of opacity, or of transparency, as measured by amount of light allowed to pass, is not proportionately the same between each contiguous two squares throughout the screen. Still, its convenience is so great that it will probably be a long time before Warnerke's sensitometer is superseded by any other.

Now as to the light. That proposed by Warnerke is a luminous tablet, prepared by coating the back of a sheet of glass with sulphide of calcium in solid paraffine. The idea is ingenious, but unfortunately it does not appear to give the very best results in practice. The amount of light emitted not only varies between one screen and another, but it also varies from time to time in the same screen, the tendency being, apparently, for this screen to become less luminous through time—that is to say, capable of absorbing a less quantity of light.

It cannot, however, be contended that a slight variation in the light used for a sensitometer is a matter of great consequence, because, although each step or degree in Warnerke's sensitometer is so great as to be represented by an advance of 33½ per cent., two contiguous squares being intended to allow amounts of light, varying as 4 to 3, to pass, yet these degrees are so fine, or rather the capacity for observation is so poor, that it is all but impossible to read to a single degree, the last two or three figures being so faint that it is almost impossible to tell just which is the last. For example, we sometimes come to the conclusion that 20 is the last figure visible, and then, turning the plate to a certain angle, we see one or two figures more. This being so a variation of, say, 5 to 10 per cent. in the light used cannot be considered to be of much moment, and, in fact, a gas burner with any good regulator does not vary so much as to render it unsuitable for use with a sensitometer, it being understood that no attempt is to be made absolutely to measure the sensitiveness of plates, but merely to compare the sensitiveness of one with another.

The method of procedure which I recommend is as follows:—One of the two plates to be compared is exposed to the burner at a fixed distance for any length of time that will give less than 25° on development. The plate is developed and fixed. A certain square is now selected, which shows a density about equal to the density of a piece of shadow density in a negative. The next operation is to give—by several trials—such an exposure to one of the other batch of plates that the same square will show the same density. The sensitiveness of the plates is then, approximately, inversely as exposure required.

I do not wish to condemn altogether the method of exposing two plates, under the sensitometer, for the same length of time, and of comparing the results after development. On the contrary, this is my own continual practice; but then I do not pretend to be able to tell with any degree of accuracy what are the relative sensitivenesses of the two plates exposed, and even the kind of idea that I am able to form is got by judging, not of the last figure, or of any one particular figure, but by taking into consideration the whole range from beginning to end, and it is the result of long practice that any useful information can thus be obtained.

When I advise that gaslight be used, I am leaving out of consideration isochromatic plates. These may, of course, not be compared by gaslight with ordinary plates, for sensitiveness to daylight. The slight difference that there is between one ordinary plate and another with regard to its sensitiveness to yellow light does not appear to vitiate the tests performed by gaslight. The plate which is most sensitive to gaslight is most sensitive to daylight (amongst ordinary plates), and to practically the same degree.

A word as to the developer to be used. There is a cry amongst some that it is necessary, before we can get a standard of sensitiveness, to have a standard developer, to use—that is to say, the same developer for all kinds of plates. Now this appears to be the most idiotic and meaningless proposal that ever was made. It seems to me to stand to reason that every plate should be developed with whatever developer suits it best—gives, that is, the best results with it.

We do not want to know the sensitiveness of a plate used with a developer which is, perhaps, particularly badly suited to it. What we want is to know the sensitiveness of a plate, as that plate is used in practice—which is, or ought to be, with the developer which best suits it. To require that the same developer be used for all kinds of dry plates, when it is a case of testing sensitiveness, appears to me to be about as sensible as it would be, with the same object in view, in regard to a wet collodion plate and a dry gelatine plate, to insist that both be developed with the same developer—with alkaline pyro, for example!

AMATEUR ENLARGING ON A SMALL SCALE.

By J. TRAILL TAYLOR.

THE problem of a simple and easy mode of enlarging for amateurs, as regards the lighting department of the operation, is still open to receive more attention.

I am the fortunate possessor of several oil lamps, whose fine Greek names do not sufficiently counterbalance the trouble in trimming the wicks (which in some instances are many), the great heat, and the unpleasant smell. Could an enlarging lantern be lighted with common gas, then, indeed, would all troubles cease, but carburetted hydrogen gas as supplied from the Company's mains is frequently deficient in illuminating qualities in a lamentable degree.

It is, however, well known to all of us that house gas may have its luminousness greatly intensified by mixing with it the vapour of some one or other of the numerous hydrocarbons. This subject has been brought before the world at various intervals during thirty years or more, and a greater or less degree of success has attended individual instances of the application. It is this system of illumination which I have thought might fittingly be impressed into the service of the photographer who, without having the mess with charred wicks and oil every time he wishes a light, might desire his appliances reduced to a gas burner and the whole preparation reduced to connecting a rubber pipe with the nearest gas bracket.

Of the various systems employed for more thoroughly carburetting gas, that which I bring before your notice is one of the *Albo-carbon* genus. I purchased it at one of our London shops for 8s. 6l., and having had it in use for some time can speak of it very favourably. Its principle consists in a piece of metal being placed above the gas flame, and which, thus becoming heated, conducts the heat to a chamber behind, which contains a hydrocarbon that vaporises at a temperature of 150 or more.

The arrangement is such that either the gas in its primitive state or after it has been enriched to saturation may be emitted at the jet, and, without having had recourse to photometry to determine the advantage, it appears to me that the intensity of the light is increased fourfold.

But in order still further to obtain the highest advantages offered by the system, I have had this modified burner constructed in which two flames are employed, one being about an inch behind the other, with an air space between. This is essential to success in obtaining the best effect.

[The speaker then exhibited and explained the construction of the gas burner to which reference had been made. By means of a socket which had a thread similar to any ordinary gas burner, this one could be lifted in or out of the enlarging lantern immediately, and by previously warming the reservoir, so as to initiate the vaporisation of the "*Albo-carbon*" inside the light, assumed its energy in half a minute after being ignited. He spoke of the disadvantage of dimensions in the flames; magnitude, he said, was not compatible with the highest definition. Hence, having first secured the required brilliance, he interposed a screen or diaphragm between the lantern condensers and the flame, and as close as possible to the latter. The aperture in the diaphragm was circular, and it varied from half an inch to an inch in diameter, the smaller one giving greater sharpness to the enlargement than the other. The position of the diaphragm was such as to hide all the light save a very bright portion selected from the most luminous part of the flame. He found it also advantageous to insert immediately in front of the diaphragm a small plano-convex lens, which prevented some loss of light by concentrating it upon the lantern condensers, at the same time that it permitted the light to be brought a little closer to them. Regretting that the bright daylight prevented him from showing in practical operation the application of this light to his enlarging lantern, the condensers of which were six inches in diameter, he showed by drawings on the blackboard by what means this system could be applied to the enlarging of negatives of larger dimensions than it was possible to utilise for this purpose by the condensers of his lantern. With the larger diaphragm, the burner shown was quite applicable for projecting pictures on a screen sufficiently well lighted for a parlour lantern entertainment.]

AFTERNOON SESSION.

THE SULPHURATION OF PLATINOTYPE PRINTS.

By H. H. O'FARRELL.

MOST of those whom I have the honour of addressing are aware that a controversy is now in progress in the photographic papers on the permanence of platinotype prints. Strong opinions have been formed on both sides, and have been expressed with an emphasis which I am afraid has at times almost overstepped the amenities of debate. In initiating here to-day a discussion on a subject deeply interesting to many who work a process of unquestionable value, I hope to approach the matter—to use a phrase now current—on its "reflective" rather than on its "impassioned" side. I would also at once disclaim any pretensions to any but the most elementary knowledge of chemistry. I am simply here to explain to you certain experiments that I have been making—experiments which any one might have made—and to offer some *crude* guesses which those of greater ability may accept, or modify, or tear to tatters, as the interests of truth may demand.

I take it that most of you know what a platinotype print is, and how it is prepared. For the benefit of those few who do not I will just mention that paper, sized or unsized, is coated with a mixture of a ferrie salt and chloro-platinite of potassium, that it is exposed to light in the usual way under a negative, and then developed on a bath of hot oxalate of potassium. Where the ferrie salt has, by the action of light, been reduced to the ferrous state, it is dissolved by the oxalate, and at the moment of solution converts the adjacent platinum salt to pure metallic platinum, which forms the image. So much is, I believe, certain, though there are probably other subsidiary reactions which are not quite so plain. The iron salt still remaining in the paper is dissolved out by successive acid baths, and the platinum salt, which is extremely soluble, is washed

out with water. There is then presumed to remain in the paper nothing but pure metallic platinum, which forms the image.

As this is an extremely stable substance, the prints have hitherto been supposed to be absolutely permanent. Monckhoven, almost alone among scientific chemists, has contended that they are capable of sulphuration, and in that opinion he has now found an unexpected ally in Mr. Andrew Pringle.

Mr. Pringle, as you are aware, subjected certain platinotypes to the prolonged action of a solution of sulphuretted hydrogen. He then found a remarkable yellowing of the prints to have taken place on the surface of the paper. I have repeated Mr. Pringle's experiments with considerable care, and can confirm the accuracy of his results as far as they go. The three series of prints which I now hand round I made on paper freshly purchased from the Company. With a view of ascertaining whether carelessness in the use of the acid baths would account for the results obtained, I gave one portion of each print one bath of acid, the second portion two, and the third three baths. The third strip had also a much more prolonged washing than either of the others. One half of each strip I mounted on cardboard for subsequent reference; the other halves were subjected for ninety-six hours to the action of a saturated solution of sulphuretted hydrogen.

They were then mounted in juxtaposition with the halves from which they had been torn. I think, for one thing, these examples clearly show that the more or less complete elimination of the iron salt has nothing to do with the discolouration apparent on the prints. This is clear, inasmuch as the third strips are in each case just as badly discoloured as the first or second. This would also show that the staining is not due to iron. You will notice that the discolouration is entirely on the image side, the back of the paper not being affected. This shows that it is not a deposit of sulphur in the pores of the paper, which would be equally on both sides.

I want you also carefully to notice that the image is in no way affected—a most important point; also that the discolouration is easily removable. The print marked C has been treated with a saturated solution of chloride of lime, which has completely effaced the stain without apparent injury to the image. The stain is not amenable to treatment with dilute nitric or hydrochloric acids, though dilute *aqua regia* seems to have some slight effect upon it.

All these things seem to show that some substance remains in the paper after the various manipulations, which is not wholly washed out and is capable of forming an insoluble compound with sulphuretted hydrogen. This may be either unreduced platinum salt or an organic compound of that salt with the sizing of the paper.

Some further experiments of mine, made with a view of determining whether this is actually the case, have not been successful. I have, however, the permission of Mr. Willis, of the Platinotype Company, to state that some experiments which he made on paper that had been exposed to peculiar conditions in America, point to the same conclusion. He believes it to be possible, by a slight alteration in the method of sensitising the paper, to obviate all danger from this source.

Anyway, it seems to me that the matter is one of scientific rather than practical interest. A discolouration that can be removed by means so simple as those I have indicated, and which, moreover, does not attack the image, still leaves the process as permanent as a steel engraving—and that is surely all that any reasonable person can desire. There is, however, one practical warning suggested by these experiments—if the most permanent results are required, pure, and not commercial, hydrochloric acid should be used in the clearing baths. The quantity of acid used is so small that the difference in cost is inappreciable.

ORTHOCHROMATIC PHOTOGRAPHY.

By W. H. HYSLOP.

BEFORE commencing my paper, I would express my exceeding regret that our worthy President has not taken this subject of "Orthochromatic Photography" out of my hands, for had he taken it up and given us the results of his careful research and immense knowledge of the subject, this would, indeed, have been a red-letter day in the annals of photography. At one time I intended to give you a sketch of the history of orthochromatic photography, but I have come to the conclusion that our time will be better taken up discussing what can be done in the future rather than what has been done in the past, excepting the last three or four years. For those, however, who care to go into the history, I would refer them to the various journals of photography from 1873 onwards. There is one point, however, in the history, which is indeed strange, and that is the great want of general interest in this most important subject. When we have named Waterhouse, Vogel, Carey Lea, Eder, Ives, and Abney, we have named, almost without exception, the only men who have written upon this subject during the last fourteen years. Why is this? Is it because we are too conservative, or is it that we have not believed in the experiments and statements of these workers?

In 1883 a patent was taken out and orthochromatic, or rather isochromatic plates, as the maker prefers to call them, were put on the market. They do not seem to have been generally successful, or brought into common use—and why? Probably because they were found unreliable, and may be further explained by the remark of a gentleman, who ought to know, that the maker was a good chemist, but he didn't know how to make plates. For my own part I think that unbelief in any chemical process of orthochrome has been at the bottom of this want of interest.

In 1885 a great cry arose throughout the length and breadth of the British Islands—and why? Because a German firm of photographers had been given permission to erect a corrugated structure in Trafalgar-square, and were allowed to photograph the national pictures. It is not necessary for me to go into the whys and wherefores of the question, but I would like to refer to a paper on the subject read before the Photographic Society of Great Britain by Mr. Bird, of the Autotype Company, a paper marked by extreme good feeling and a desire to give to an opposition firm the full credit due to them. The paper was illustrated by many examples of Messrs. Braun's pictures, as well as by photographs taken some years earlier by a Berlin firm, and showing the great advance in the rendering of the various colours. In the discussion which followed, it was, I think, the general opinion that the retoucher's pencil and brush had more to do with the change than any chemical means, and I would just quote "Free Lance" in THE BRITISH JOURNAL OF PHOTOGRAPHY of May 29, 1885. He says: "Mr. Bird's remarks, temperate and well thought out, are well worthy of being remembered, and, while leaving to his hearers the task of coming to a conclusion as to Messrs. Braun's mode of producing these excellent copies, he enables one to make a shrewd guess at his own opinions. It is true that the photographic public have for some time had before them details of a method of photography of great novelty; but, as the lecturer said, 'they were not impressed with laboratory experiments—they remember many discoveries that came to nothing and improvements that were delusions; they are not credulous of the practical application of new ideas.'"

"These remarks are not more disheartening than true, and the condition described is not to be explained upon any single basis only. Many photographers rarely read a scientific article; others are indifferent, and prefer only to accept acknowledged facts, trusting to their commercial instinct giving them the ultimate advantage over their more scientific brethren; perhaps, most potent of all causes still, others have had such experience of reputed grand discoveries which have eventually proved to be ignominious failures, that they become wearied, and only try fresh plans when they are shown to be commercially successful by the touchstone of experience. It would be impossible for one man to try all the new processes invented and published; and a few years' experience will show that those ushered in with the most blatant assertions of excellence are usually the least meritorious, and those deserving, yet modestly proclaimed discoveries, get shelved. As Mr. Bird plainly puts it, photographers have had before them full accounts of a method of taking photographs in which colours are represented in a true scale of tones, but they have not adopted the process. Messrs. Braun have produced copies of oil paintings far superior to any previous work of a similar character; do they owe their success to clever retouching or to some modification of processes not new? We have, through the writer, Messrs. Braun's word that the latter is practically the case, and we have no right to doubt their word. They lead us to infer that the method is complicated, and this is what might reasonably be expected; further, we are told they will keep their knowledge to themselves as long as they can, and for this also no one can possibly blame them. If the improvement in Messrs. Braun's pictures should be owing to new chemical methods, photographers may rest assured that they will have to bestir themselves and do likewise; they cannot afford to be stationary."

Notwithstanding the talk at the time, the subject seems to have slumbered again, and for eighteen months nothing much was heard of it; but a time of awakening came, and all credit is due to Messrs. Dixon & Son for that awakening. The gentleman who has an interest in the Tailfer patent for this country has at the various societies' meetings done his best to minimise the services of Messrs. Dixon, but I am quite sure that I am not alone in thinking that, had Messrs. Dixon not issued their successful plates, we would never have heard so much of the Tailfer patent, nor would the gentleman have bought the English interest in it.

I now come to my own experiments, and I will give you formulæ, and show examples from the plates prepared by the various formulæ. The plates used in the following experiments are ordinary commercial plates, and the only care taken was that they should all be from the same batch. It has been said by the unbelievers that the orthochromatic effect is a mere matter of exposure; that, supposing you expose an ordinary gelatine plate behind a yellow screen, and long enough, you will get quite as good an effect as by the staining process. I have never yet heard any of them say how long the exposure should be in order to get the desired effect, but on the card marked A, which will be passed round, you will find prints from ordinary plates exposed on this particular board, with and without a yellow screen; the first was given ten seconds without the coloured screen, the others thirty and sixty seconds and five minutes with the screen.

If you examine the prints you will find that in the one exposed ten seconds there is no orthochromatic effect whatever; the light red is fairly good, but the other colours are in exact opposition to what they should be. In the thirty seconds one you will find that the violet and dark blue are darker than in the first, but you find also that the orange and yellow are darker, too, and the light red lost entirely; the sixty seconds plate is, I think, no improvement on the thirty seconds. We now come to the one exposed five minutes, or ten times the normal exposure, and here, I think, we get an improvement. We get the light red back again, but otherwise there is very little difference. I think these examples clearly

show that, to use an ordinary plate, exposing it a fair length of time and expecting to get a good orthochromatic effect, is not at all practical.

I will now take the series marked A. You will find at the top of this and all following cards a print from an ordinary plate exposed without screen, so that you may compare the various results with it. The first two you will see are from the Tailfer plates; they give a fair effect, but I may tell you that in order to get the two negatives I exposed two dozen plates. I couldn't keep the films on the glass; every known means was tried to save them before and after development, but all to no purpose. You can easily understand, if this kind of experience befell many who tried them, why their progress in this country has been so slow. The next two are plates prepared by myself, according to the specification of Messrs. Tailfer & Clayton, and exposed with and without screen.

I had tried this specification some time ago without success, and Mr. William Bedford stated at one of the Society's meetings that he had not been successful; but in order to give it a fair trial I tried it again with a like result. The examples give no more trace of orthochromatic effect than do ordinary plates exposed with screen for thirty seconds, and yet these are treated with tetrabromfluorescein, one of the claims of the patent.

The third pair on the card are Edwards's isochromatic plates, which give good rendering of blues and yellows, but at the expense of the reds, and this fault is, I find, in all the commercial orthochromatic plates. And at this point I should like to make an assertion, and for this reason: Mr. Edwards stated, at the last meeting of the Photographic Society of Great Britain, that his plates would give a good orthochromatic effect in daylight, and without coloured glass. Now I most emphatically state that there are no plates in the market which will give such an effect without a screen, and I very much doubt if anything but a collodion-bromide plate, treated, will give a result different in any way from an ordinary gelatine plate. You can judge for yourselves by looking at the examples.

And now let us turn to another card, B, and first of all we have Dr. Vogel's azaline plates. For some time past a great question at photographic meetings has been, What is azaline, and where can you get it? I have tried many places for it, but have never found it; so when the learned professor took out his patent some weeks ago, I thought I would find out now, but no; I am as much in the dark as ever. The doctor does not claim azaline, but simply all colours which readily fade when exposed to light. However, it does not much matter what it is, for, if the plates I had from his agent here are a fair sample, you can easily see their colour-sensitive qualities are very poor indeed.

The next two examples are from plates of my own preparation, and I think, if you look carefully at them and compare them with the examples from Dixon's plates, underneath, you will say they are in no way behind, and that in some things they are well ahead of, the commercial plates. The improvement is in the reds, and they give generally a better gradation. The great trouble with them, however, is that they do not keep, and that you must pour on the bromide and ammonia first before the pyro, or else you will get silver stain; but for any who wish to have a really good plate giving good gradation, and if they can prepare them the night before requiring, the above will give good effects.

The formula stands thus (stock solution):—

Erythrosine	1½ drachm.
Ammonia 88°	1 "
Alcohol	6 ounces.
Nitrate of silver, 1 drachm, converted into chloride with hydrochloric acid, thoroughly washed, and redissolved in ammonia and water, bulk made up to	2 "

To make up the bath take—

Stock solution erythrosine	1 drachm.
Chloride solution	20 minims.
Liquid ammonia 88°	1 drachm.
Water	6 ounces.

Place this solution in any convenient vessel, and bathe your plate for one minute; then wash well under the tap and put it aside to dry, which it will do in a few hours.

I was asked last night by a member of the Club, what light should be used for the preparation and development. As the change in the nature of the plate does not take place until dry after treatment, it is not necessary to use a very weak light. I use orange glass behind ground-glass, and have not found any fog from it. I use the same for development, only taking care that direct light does not fall on the plate until the image begins to appear, after which the plates seem to stand quite as much light as ordinary.

On card C, you will find examples from plates prepared with what is sold as eosine B. I am not chemist enough to know the difference between this and plain eosine, but you will see that plates prepared with the plain solution and others prepared with an addition of silver have no orthochromatic effect.

Series D gives examples of plates bathed in a solution of Magdala red, a dye mentioned by Dr. Vogel, and said to have good effect. I have not found it so.

Series E are examples of chlorophyl plates, the favourite process of Ives. I fancy there was something wrong about my chlorophyl, although

it was from what is known as blue myrtle, but at any rate I got little effect from it.

And now we come to the last card, F, and on it you will find prints from plates prepared with erythrosine plain and with the addition of citrate of silver; this last has no advantage over the formula given. I am very sorry that I have only had photographs from the coloured board to show; had the weather been favourable, I had hoped to have had a few landscapes, taken with and without the screen. At the meeting of the Photographic Society of Great Britain, when this subject was discussed, the question was asked whether negative paper could be treated. I replied to the effect that it could; and I have here to-day a few orthochromatised stripping films, which any who care to see may examine. And now, in conclusion, I trust there will be a good discussion, and that no more will this important matter be allowed to slumber, for why should we be content with error and untruth when we have the means at hand to make it otherwise? We will be well paid for any trouble in the preparation of plates by the enhanced beauty and charm of our productions.

RATIONAL DEVELOPMENT.

By ANDREW PRINGLE.

I HAVE some reason to fear that we are all of us too apt to look upon development as a mere mechanical, or chemical, or at least technical operation, necessary certainly, but objectionable, and unimportant so long as we get a negative that will yield us technically good prints. But I have equal reason to know and to assert that this is a very erroneous and very fatal view to take of one of the most beautiful phenomena to be found in science, of one of the most interesting actions observable in nature. With the beauty of the operation I have nothing to do at present; if any one deny it he must be curiously constructed. My point is to try to show the importance of rational development in the production of artistic photographs, and also to inculcate intelligence in the operation of development.

I wonder how many British amateurs have ever tried the effects of different systems of development upon plates, equally exposed, on the same or similar subjects. I wonder how many amateurs could say, even in a general way, what are the results of slow and rapid development, of abnormal quantities of the reagents and the restrainers, or even of the various kinds of development—pyro, ferrous oxalate, and so on. A great many amateurs, I fear, could not answer in a satisfactory or assured way at all. There is too much of the "15 drops of A and 5 of B" knocking about for satisfactory answers. "A thing that will print" is the definition of a negative for far too many people.

Now the immediate object of my remarks is to draw attention to the effects of modifications in development, and to suggest how we may use these modifications, so as to get not merely what we call "good negatives," but negatives that will give us prints correctly and artistically reproducing our subjects, and, moreover, reproducing them in the aspect we desire. When we buy a dozen plates, we get with them a formula more or less arbitrary and intricate; these formulae are useful, as suggesting the normal qualities or the weak qualities of the plates. For instance, when, with some trouble, I have analysed a developing formula, and find an unusual quantity of pyro, I at once suspect that batch of plates to be one likely to give me thin, poor negatives, unless I take care. When, on the other hand, I find the formula gives a less than usual quantity of pyro, I expect a plucky, perhaps hard, negative, apt to want half tone. When I find the alkali larger in proportion to the restrainer, I suspect the maker of a wish to get for his plates a reputation for great rapidity; and when I find the restrainer powerful, I expect a plate with just a tendency to fog, or else a plate intended to allow of a long exposure, such as some workers seem to demand. Every time that I get a new make of plates I analyse the developing formula, and carefully note the proportions of the ingredient, but I never attempt to make up a formula precisely in the arbitrary and, as a rule, intricate manner formulated. But surely, no man in his senses can ever dream that any one formula will suit every case; any one who has developed a dozen negatives must surely know better than that. And yet I venture to say that a vast majority of us try to develop all our plates alike, be our subjects what they may. Mountains, waterfalls, glens, churches—outside and inside, clouds, seas, glaciers, coal-mines—all alike, "15 drops of A and 5 of B." That is what the maker's formula says, and who should know, if the maker of the plates does not? After our development has gone a certain length we find the need for modification, but we always begin with the formula. Now I want to chuck formula aside altogether, and use intellect instead. A formula ought to be simply a convenient method of keeping our reagents, and—the important point—of getting precisely the quantities of reagents that we require. A formula cannot be too simple. Plate makers and many other people seem to think a formula cannot be too complicated, for among the many formulae I have seen I find all sorts of queer odd numbers of grains and drachms, ounces avoirdupois, and ounces chemical, Winchesters, pounds of various kinds—in fact, every kind of figure to confuse and annoy one. There is nothing talismanic in half a grain, nor any virtue in such a number as 7½. What we want is to get, without trouble or loss of time, a certain quantity, not of A or B, but of certain known chemicals. The "A" and "B" business has spoilt, in my humble opinion, a vast number of amateur photographers.

They rack their brains to calculate how much they require of A, even if by chance they know the chemicals which compose A, and they do not think how much pyro, or alkali, or bromide they require. A formula should be of such a nature that you can't measure it without knowing how much of its essence you require. Now, I do not care what strength we make our solutions so long as we know precisely what they are, and how to extract from them precise quantities of our reagents, but for development I find ten per cent. solutions by far the most convenient. Everything that is not used stronger than ten per cent. I keep in ten per cent. solutions—pyro, ammonia, bromides, citrates, potash, soda, gold chloride, soda acetate, &c. Put an ounce into a measure, and make up to ten ounces after solution—that is the whole affair, and ten minims are always equal to one grain; or, put in a drachm, and make up to ten drachms; or, put in fifteen grains, and make up to 150 minims. In all cases ten minims equal one grain. The advantage of this, or a similar method, is that one is bound to know what quantity of reagent is used, and so development becomes an intelligent, not a blind operation.

One formula, in particular, appears to me of the "talismanic" order, which quality accounts, no doubt, for its seeming popularity among amateurs. I hardly ever see an amateur paper without some question or other about the "Beach" Developer—so called, I understand, after the illustrious President of the New York amateur society. I confess I never made up a developer in this precise fashion, so there may be in it some virtue unknown to me; but as it stands in the ALMANAC of this year, it looks to me anything but promising. In the first place, it is a mixture of avoirdupois ounces—not exact—and chemical ounces, which is a bad start. Then it contains a very extraordinary proportion of sodic sulphite when the developer is mixed complete. I cannot see any need for such a quantity, even if sodic sulphite is the best, or a good, preservative, which, lately, I have begun seriously to doubt. The pyro solution looks something like ten per cent. (Mr. Beach states that one drachm contains six grains of pyro, which means ten per cent., but I have not tested this), but the potash is an arbitrary measure, and calculation is required to discover how much potash we have in "twenty minims or a quarter of a drachm." The developer may be a good one, but it is certainly not a simple one, and simplicity is important if we are to work with intelligence. If you want a good and perfectly simple pyro solution, dissolve a chemical ounce of bisulphite of potash in about eight ounces of water, and mix in a chemical ounce of pyro, finally making the bulk to ten ounces. As pyro is sold in ounces of 437½ grains, if you want to be very accurate, make the bulk to 4375 minims=9 ounces 55 minims. This requires no addition, works beautifully, and keeps for a very long time. I ought to say that I get my bisulphite from Messrs. Mawson & Swan, under the name of "meta-bisulphite of potash." I can discover no difference between it and the ordinary bisulphite.

Never, on any consideration, should the chemicals be mixed. For years I kept my bromide and alkali mixed, but I look back upon that time as a sort of nightmare. I cannot understand why for so long I deliberately handicapped myself in the race. It seems monstrous to bind yourself in such a way that you can't get ammonia without bromide, except by having extra separate bottles. Nowadays I would as soon put hypo into my ammonia or pyro as bromide. The great advantage of keeping each chemical separate is patent when we consider my next point, which is that very seldom ought two consecutive negatives to be developed precisely alike, that is if we are to carry out intelligent development. If our two consecutive plates were exposed on the same or similar subjects, then, after our first is developed and examined, we may be able to improve the next by modification of development. If the subjects are different the development ought probably to be different, and this brings me at last to the real gist of my argument.

I say different subjects require not only different exposures but different development, and on the development depends, not only the technical quality of our negative, but also the artistic quality of our prints. If anybody present is inclined to sniff at this statement, let me ask him to use a very convenient line of reasoning, namely, an extreme case. Take an interior, a dark one lighted here and there by windows. Certainly a negative of such a view would not be developed in the same way as an open landscape negative. These are, perhaps, the two extremes, but between these there are an infinite number of gradations, some of which I will touch upon.

When we have a wide open landscape without any marked foreground, we are certain to run a risk of wanting contrast, as well as fog in the distance. I would develop such a negative *stoutly*, with plenty of restrainer and pyro, but I would develop it fully. An interior is different; we are certain to have violent contrast, so I should, in that case, keep down or omit bromide, use very little pyro, but a good strong dose of alkali, and I would not develop it nearly so much as I did the open landscape. Take the case of a landscape not stretching to any great distance, but having a dark foreground of foliage. What we have to fear is the distance becoming too dense before the foreground has all its detail out. Here again I would certainly begin with little bromide and pyro, but a good dose of alkali, and as soon as I had the dark details out I would add pyro, and bromide and alkali, if required, and this negative I should develop rather quickly, compared with my open landscape, for long development means contrast, *ceteris paribus*. When I fear under exposure, I keep down pyro and restrainer, and I rather concentrate than dilute my developer. I do not believe at all in the system of watering

the developer in such a case, though I know it is recommended by some. I have made many trials with various developers, and I always succeeded better with a short and sharp developer than by watering and waiting. It seems to me wrong, both in theory and practice, to play the watering trick.

We require not only to consider our *fears*, but our *hopes*, when we make up a developer. When we selected our view and made our exposure, we had, or ought to have had, a specific idea and a specific intention. We meant, or ought to have meant, to give our view some particular rendering to cause it to convey some particular sensation to those who are to see our print. We expose, or ought to have exposed, with this intention in our mind, but our exposure may be multiplied by our development; and our development, if not conducted appropriately, will either spoil our negative in *technique*, or, by a discreditable fluke, will cause us to produce a print different, or possibly contrary, to what we intended. So when we start to compound our developer, we must consider what we require as well as what we fear. I am well aware that some people plume themselves on trusting entirely to their exposures, and do not even take notes of their subjects, but develop all their negatives alike, and blindly; this sort of work may sell, but it is not what amateurs want. We want expression in our work, not topography merely. Now in development we have a mighty instrument for rendering expression. It is, however, impossible to lay down rules hard and fast for the use of the developer under this head, but I shall give a few very general hints on the subject. Lightsomeness, brilliancy, contrast, *allegria*—it is hard to find a name for the quality—may be expressed by slow development, plenty of pyro and bromide, and full development. Gloom, mystery, age, and "all that sort of thing, don't you know?" are more likely to be expressed by a small quantity of pyro, with just enough alkali to give the details required, and in this case the development may be shortened.

In portraiture, development should not be carried nearly so far as in landscape, and just enough density should be acquired to hide facial colour defects. If an outdoor group can be made into a good picture at all, it will probably be done by a good quantity of pyro, and alkali sufficient to bring out all the detail. But I find groups very difficult on account of the diffusion of the light.

In regard to the alkalies used for development, there seems to be a considerable diversity of opinion. I always use ammonia when I can, but I have no particular objection to soda and potash. Using ammonia, you can have no restrainer if you choose, except that "evolved" from the emulsion; with potash and soda, you have a restrainer whether you like it or not. If my plates are not tolerant of ammonia, I put them in the fixing bath unexposed, but I have lost far more plates from using soda and potash than ever I did from red fog, unless I was using very old plates.

What we require in development is to think. We shall never advance a step if we do not know precisely what we are using, and if we develop blindfold our successes are half flukes and our failures serve us right. Away with all unknown and mysterious mixtures, and go for developing formulae to the fountain head, to the chemicals themselves, and not to *empyreal* bottles—that must be a mistake, surely! *Empyreal* bottles, that's it. And don't go mixing bromides and alkalies together, incompatibles in development, nor avoirdupois and chemical weights—in fact, never mix your liquors at all till in your (developing) cups.

A VILLAGE PHOTOGRAPHIC EXHIBITION.

THEALE, a Berkshire village of about 800 inhabitants, away "far from the maddening crowd" of any town, has just held its photographic exhibition. Through the exertions of one of its residents—an amateur—it has got together a goodly gathering of photographs, representing the work of some of our leading professionals and amateurs. Six silver and six bronze medals have been awarded.

Framed photographs to the number of 285 find place in the village school, a room about forty-four feet long by twenty feet wide, and if all are not well lighted the architect of the building is not to blame, nor the hanging committee that all are not hung "on the line."

A class room adjoining is temporarily darkened, and occasional shows of lantern slides take place. An oil lantern displays the beauties of the slides on a screen of tracing cloth, which stands between the lantern and the spectators. A goodly lot of slides has been lent for the purpose.

The catalogue leads off with a list of patrons, the committee, and the local train service, followed by an address to the visitors by the Hon. Secretary, Mr. A. A. Harrison, the enthusiastic promoter. The list of exhibitors numbers seventy-eight, of which twenty-seven are marked by an asterisk as amateurs. A space is devoted to advertisements, but prominence is given to the local grocer and baker, the horse-collar manufacturer, the stationer and medicine seller; while later on plates, lenses, apparatus, "cheap," "reliable," "quick," "unsurpassed," "efficient," "unobtrusive," are well mixed up with Brown's cod-liver oil, church services, mineral waters, and home-cured bacon. The rustic anxious inquirer after the cost of apparatus will probably be disappointed to find by the advertisements that a camera costs 20s., a lens 9s., and sliding legs (best make) 12s. 6d.!

There are many fine photographs on the walls by professionals, mostly familiar to visitors at the recent London Exhibition. The prices in many instances are put, ranging from ten guineas to 8s. 6d. Amateurs have responded to the invitation to a somewhat less extent, but there is some very nice work to be found for the looking, one exhibitor estimating the value of his views at £1 a-piece; while another, with an asterisk before his name, which should imply "amateur," informs the public, in large print on his exhibits, of his great merit, and gives a list of medals he has gained. It is gratifying to find that the local photographers, amateur and professional, have come well forward with their contributions. There is a good show of apparatus on the table, and the most recent inventions and appliances. All round, Theale has shown admirably what can be done with pluck and energy. To quote from the address "To the Visitors," "So far as we know this is only the second Photographic Exhibition which has been attempted in a village, but we think we may with pardonable pride ask our visitors if the result of our efforts is not worthy of imitation."—[Yes! most certainly.—Eps.]

Department for Inexperienced Photographers.

THE USE OF A SWING BACK AND THE EFFECTS OF TILTING THE CAMERA.

It is quite pertinent that an inexperienced photographer should inquire—What is the use of a swing back to a camera, seeing that it increases the expense, adds to the bulk, and that good photographs can be taken without it? All this is quite true, and yet it has certain uses which we shall proceed to indicate.

Let us suppose that the subject to be photographed is a rather tall building, the top of which cannot be got quite into the plate. One naturally tilts the camera, or points it a little upwards, until the image of the building has assumed its proper place on the ground-glass, for of course the higher it is pointed upwards the lower is brought the image of the building on the plate. We know very well that the same thing can be achieved, in a modified degree, by sliding the lens as high up on the camera front as it is possible to do, but this implies the employment of a lens embracing such a wide angle of subject as to permit it to cover a field greatly exceeding the dimensions of the plate.

When the top of the building which we have impressed into our service for illustration can be got properly in by raising the front, and at the same time keeping the camera quite level, all is well, and a rigid bodied camera will certainly answer in this case as well as any other. But this will prove exceptional.

By tilting the camera upwards the whole building has now been got nicely on the plate. It may, or may not, all be sharp in focus, but this is of no consequence to us at this stage of the illustration. Observe, however, that by the mere act of tilting, or pointing the camera upwards, the back has been removed from its normal vertical position when standing level. Now as it is a principle in all projection that when photographing a vertical object, like a building, the sensitive plate must also be in a vertical position, the consequences of this non-agreement of building and camera back as regards both being vertical are that the photograph will be distorted. The middle of the image will be all right enough from top to bottom, but the sides will converge and be quite off the perpendicular.

We shall now show wherein a swing back remedies this evil. When a camera possesses this appendage, after the instrument has been tilted and the subject adjusted it is only necessary to loosen the screw by which the back is made to retain its place, and bring the ground-glass to a perfectly vertical position in order to ensure the image being projected on the ground-glass with rectilinearity.

It will be instructive to focus a house or any square object, and then watching the effect upon the sides of the ground-glass while the back is being swung out and in alternately. Convergence and divergence of the perpendiculars will thus be induced in succession.

In ordinary landscape photography, especially when employing a large camera and a lens of long focus, the swing back is frequently of great advantage in getting the delicate shrubs, grasses, or flowers in the immediate foreground quite sharp, which cannot always be done if the camera has a rigid back. After getting the distance quite sharp, swing the top of the camera back so as to be farther from the lens than when in its ordinary square or normal position. By doing so, it will be found that the foreground objects, formerly rather out of focus, will now be rendered exquisitely sharp. If the camera be so constructed that the ground-glass is pivoted at the centre of its sides no refocussing will be necessary, as the distance will suffer no change; but if it swings by a hinge at the bottom it will be necessary to refocus the centre, as by the tilting of the ground-glass the previous focussing of the centre is disturbed.

THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at the ordinary monthly meeting of the above Society, held at 5A, Pall Mall East, London, the President, Mr. James Glaisher, F.R.S., occupied the chair.

Mr. W. F. DONKIN, the Hon. Secretary, read the report of the Council for 1886, which set forth that during the year important advances had been made in orthochromatic photography, and that a period of calm had settled down in relation to researches into the chemistry and philosophy of gelatine processes, in which much success in working had been attained. Valuable germs of theory had been brought forward during 1886, to bear fruit, perhaps, in subsequent sessions. The annual Exhibition had displayed a greater knowledge and advance of art than its predecessors, and numbered among its visitors the Duchess of Teck and her daughter, the Princess Victoria. Mr. T. Sebastian Davis had given valuable aid at various lantern evenings held by the Society. At the Exhibition 1296 separate photographs had been on view, and there had been a larger number of visitors than on previous occasions; the exhibitors had displayed greater skill in introducing figures into landscapes, and a greater tendency to give photography the attributes of a fine art. The pictures on receipt had been divided by the judges into four classes before they knew the names of the exhibitors; the first and second classes were given the best places, the third class then had its turn, and the fourth class was left for final judgment. The report expressed regret at the paucity of scientific objects at the Exhibition, more especially in the matter of solar, stellar, and planetary photographs. Fifty-four new members had been elected during the year, and but few had resigned during the same period.

Mr. W. S. BIRD, the Hon. Treasurer, read the Treasurer's report for 1886, which recorded £22 11s. 11d. in favour of the Society as compared with the previous year, so the funds were in a healthy state; indeed, the subscriptions for 1886 were the highest of any year in his record. It was desirable that the Society should have a permanent home, a library, and a laboratory; practical difficulties stood in the way of obtaining them, which, however, were but difficulties to be overcome. He thought that it would be well to have one or two distinguished artists on the jury of the Exhibition; still, whenever that had been the case there had been more complaints from exhibitors than usual; he should like to hear the opinion of the members upon this point. The Council thought of appointing a committee to consider whether the *Journal* of the Society should be issued less frequently, as such action would much reduce the expenditure thereupon. The Society usually made a clear profit of £40 or £50 by each of its Exhibitions. Among the expenses of the past year was an item of between £3 and £1 for the travelling expenses of the Assistant Secretary whilst making inquiries as to alleged injuries to the frames of pictures sent to the Exhibition; the complaints had been discovered to be well founded, and the injuries consisted chiefly of scratches, apparently due to the friction of the frames against each other; nails and projections in the backs of some of them had much to do with it; so, whilst the Council would devote special care to the matter in the future, it was hoped that exhibitors would aid by putting their pictures in frames with flush backs. The bringing out of the little book on Platinotypy cost £16; each of the members had received a copy, and 300 were left for sale to the public. During the year £50 had been invested in Consols, making £150 there altogether. What with that money, and with the cash in the bank, and the property possessed by the Society, it had in hand the equivalent of £528, and no liabilities; that was its position at that day.

Votes of thanks were then passed to Mr. W. S. Bird, the Treasurer; to Messrs. Ince and Francis Cobb, the Auditors; and to Captain Abney, the Editor of the *Journal*.

The Scrutineers reported that Mr. James Glaisher had been elected President; Mr. H. P. Robinson, Vice-President; and Messrs. C. E. Abney, Francis Cobb, T. Bolas, W. K. Burton, W. F. Donkin, J. Traill Taylor, and Colonel H. Stuart Wortley, members of the Council.

Votes of thanks were then awarded to the acting Scrutineers, Messrs. Standell Addenbrooke, and W. M. Ashman.

Mr. T. SEBASTIAN DAVIS proposed a vote of thanks to the President, who

had been in that position, he remarked, for seventeen years; this was seconded by Mr. WILLIAM ENGLAND, and carried with acclamation.

The PRESIDENT, in returning thanks, said that any one who occupied that or any other official position in the Society should do his duty; at the beginning of every year he made a list of the days in the year upon which it would be his duty to be present at the transaction of the work of the Society.

Dr. DONKIN, in response to a vote of thanks to the Hon. Secretary, said that, as he had stated on a previous occasion, all the thanks were due to the Assistant Secretary, Mr. Cocking. All he (Dr. Donkin) did was to read the annual report.

Mr. JAMES B. SPURGE then read a paper upon *A Method of Estimating Photographic Deposits with reference to the Printing of Negatives*, which memoir was illustrated with diagrams and accompanied by tabular statements. The measuring instrument used was a Spurge's sensitometer, consisting of a number of different-sized holes in a brass plate, each bored with micrometrical accuracy, and all bearing a definite ratio to each other in aperture; behind each hole is a short rectangular blackened brass tube, open at the end farthest from the brass plate, and against the open ends of all these tubes the plate to be tested is placed; thus the sensitive plate forms the back of a number of little blackened chambers, into each of which light enters through a hole of a particular size at the opposite end. The author said that the object of his paper was to set forth a method of defining the effect produced upon a sensitive film by the combined action of the developer and of the exposure to light which it has received; consequently several parts of the film must receive a series of exposures bearing a definite ratio to each other, and this could be done by the aid of the sensitometer which he and Mr. Mucklow introduced to the notice of the Society in 1881. The sensitometer had the advantage of a fixed range, the relative amounts of light being independent of any variation in the intensity of the illumination; the results also show any defect inherent in the film, such for instance as granularity, because no medium intervenes between the light and the film under examination, for such medium is always liable to introduce its structure or other defect into the results, and to mask the effects intended to be observed. The instrument also had the advantage of exhibiting inappreciable deterioration with hard wear. The ratio of the sensitometer is 1 to 1.2599, or four to five; every third chamber receives double the amount of light, and this condition is found to be constant within very narrow limits, whatever be the method adopted to illuminate the pierced plate, provided the light emanates from a sufficiently large surface, such, for instance, as from the surface of a sheet of opal glass. Prints thus obtained upon platinotype and upon albumenised paper give a very near approximation to a constant, but such is not the case with sensitive bromide of silver films. Upon developing a gelatino-bromide film which has been exposed behind a negative a deposit is obtained, which varies inversely to the opacities of the negative; he preferred to view this result as caused by the light being reduced in actinic value after transmission, as compared with its value when incident. The author here described at some length his attempts to prove that the ratio of the transmitted to the incident light is a constant for various degrees of opacity in differently coloured media, when measured with gas and bromide films, or with solar light and albumenised paper; the opacities were found to agree well together, notwithstanding great differences in the exposure and great variations in the intensity of the incident light. One object of the author's paper was to show a means of determining with certainty the range of any photographic plate, and of being able so to specify the range that a plate-maker should know from such specification exactly what description of plate is required, and whether he has met the requirement. In one of Mr. Spurge's diagrams of results, it was shown by plotted-out curves that the density of a negative does not increase proportionately to the exposures, and the advantages for quick printing of negatives of low initial density were graphically indicated. He set forth, also, the values of the influence of the plain glass and the film of plain gelatine upon the printing properties of a negative. Of the influence of a dirty atmosphere, in which, as in towns, notes of solid matter are floating, Mr. Spurge said that such notes reflect light according to their nature and to their number; when they are opaque and in focus, they reflect equal amounts of light upon all parts of the film while they are in transit, and so will lessen the indicated range of the subject which is being photographed. A subject possessing few contrasts can have those contrasts photographically increased by placing an absorbing medium between it and the film; this will have the same effect as staining in the case of negatives, with the exception that the disturbance will be greater in the shadows than in the high lights. He hoped that his remarks would hasten the adoption of means of comparing results in a manner which can be generally recognised, and which results shall be universally comparable one with another; any process, developer, or mode of manipulation will then quickly drop into its proper place in the order of merit in relation to its predecessors.

A vote of thanks was awarded to Mr. Spurge for his paper, and the discussion was adjourned.

Mr. C. Wray Palliser and the Rev. C. H. Sutton were elected members of the Society, and the meeting broke up.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, February 3, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. A. Cowan presided.

Mr. F. M. Edwards gave a demonstration of the development of platinotype prints by gently drawing the exposed proofs through a hot solution of potassic oxalate and then immersing them in successive baths of water acidulated with hydrochloric acid; the resulting pictures were fine ones, with rich and deep blacks.

Mr. W. WILLIS said that the paper was sensitised with a mixture of ferric oxalate and potassic chloroplatinate, and that the light acted almost entirely upon the iron salt, reducing it to ferrous oxalate, which developing substance was therefore formed in close contact with the platinate salt. He first discovered the method by means of a test-tube experiment because he had pre-

viously come to the conclusion that ferrous oxalate ought to reduce a salt of platinum; at that time no solvent was known to him for ferrous oxalate, until he saw in Watts's *Dictionary of Chemistry* that the French chemists, if he remembered rightly, had discovered that it was soluble in neutral potassic oxalate. Such was the early history of the thing.

Mr. A. MACKIE asked if other salts could be used for development. Mr. WILLIS replied that he had indicated a great many. At one time he thought that oxalate of potash was only a solvent in the matter, but now he thought that it added to the reduction, but it did not account for the evolution of CO₂ during the reaction.

Mr. Edwards exhibited a print upon paper which had purposely been allowed to get damp before exposure under the negative, to show the general degradation of the picture thereby produced.

Mr. A. L. HENDERSON asked what was the speed of printing. Mr. EDWARDS responded that the time of exposure was about one-third of the time necessary with the ordinary albumenised paper printing. He here exhibited a picture he had just developed of the new marble bust of Mr. Glaisher.

Mr. MACKIE remarked that it was a portrait of "The Grand Old Man." Mr. J. B. B. WELLINGTON had tried to print on platinotype paper by gas-light, by giving an exposure close to the light for half an hour, but could obtain no impression.

Mr. WILLIS stated that he had been able to print upon the paper at a distance of eighteen inches from a powerful electric light, but, practically speaking, daylight was necessary for everyday work. He thought that he should be able to bring out a platinum negative process, not of commercial value, but proving that the smallest action of light had a little effect.

Mr. EDWARDS here developed a picture much larger than the bath, by drawing it through the solution one part after another; he said that in so doing it was necessary to take care that the paper did not touch the hot sides of the bath outside the solution, for that would stain the print.

Mr. HENDERSON asked what was the effect of leaving the prints longer upon the developing solution.

Mr. WILLIS replied that the lights developed almost instantaneously, but that a little more could be obtained in the shadows by longer development.

Mr. MACKIE asked if the temperature of the bath were a matter of importance.

Mr. WILLIS answered that it determined to a certain extent the character of the image; by development at a low temperature a more granular deposit resulted, and a transparency more like the transparency of an engraving; also, with a cooler bath errors in exposure could be counterbalanced to a certain extent; by its means, also, too much strength of image, due to over exposure, could be avoided. It was possible to develop upon an absolutely cold solution. The paper could be prepared, if desired, so that it could be used with thin negatives.

Mr. J. W. COX asked why he obtained different colours from different negatives.

Mr. WILLIS was unable to give an accurate answer to that, he was sorry to say; the fact was that in those cases in which a brown was produced the image undoubtedly was not all in metallic platinum; either one of the oxides was present or platinoous chloride, and giving a warmer tone. To produce sepia-looking pictures, he used a different developer; he regarded the brown proofs as permanent; they were acted upon by strong hydrochloric acid before they were dry, but he had never been able to act upon them with it afterwards; even those brown images were very largely composed of metallic platinum.

Mr. HENDERSON asked how long the paper would keep in good condition if kept perfectly dry all the time.

Mr. WILLIS replied that that was an unknown quantity, but he could say with almost absolute certainty that it would keep good for two months. Sometimes paper a year old proved to be as good as new, but, as a general rule, he gave two months as the life of the paper, even when kept all the time in a tube with chloride of calcium.

Mr. J. HUBERT asked what negatives were best for the process.

Mr. BRIDGE said that very often the getting of the best negatives for the purpose was only a matter of proper exposure.

Mr. WILLIS remarked that Mr. Edwards could best speak on the point, since his experience was so great.

Mr. EDWARDS stated that good vigorous negatives with proper gradation were the best.

Mr. J. TRAIL TAYLOR said that Mr. O'Farrell had told him that a negative had been sent to a certain society as one which was very unsuitable for platinum printing, yet he (Mr. O'Farrell) obtained excellent platinum prints from it.

Mr. EDWARDS remarked that he would now lay before the meeting some pieces of the actual platinotype prints which had been yellowed with a sulphide by Mr. Pringle, and which they would see had Mr. Pringle's handwriting on the back; he had put fragments of them into a little weak chlorine water, which had removed all the yellowness, and they could piece the portions so restored with adjacent pieces which he had not submitted to chlorine water, so that they might see that the treated parts of the print had been restored. Some pieces of developed bromide of silver prints submitted to the same treatment with chlorine had none of the image left.

Mr. HENDERSON stated that Mr. Edwards had restored to whiteness some pieces of platinum prints which he (Mr. Henderson) had discoloured with Schlippe's salt.

Mr. A. HADDON had put two pieces of a platinum print which Mr. Edwards thought could not be discoloured into sulphuretted hydrogen water to which a little ammonia had been added, and they changed colour; he restored the whites of one of them by dipping it into weak chlorine water. He then exhibited a platinum print which had been discoloured by the age of the paper; the discolouration might be due to the presence of iron yellowing under the influence of the sulphuretted hydrogen present in small proportion in the atmosphere. Or might it be due to some combination between the iron and the gelatine used as a substratum in the preparation of the paper? In the latter case a powerful solvent like chlorine water might be necessary to remove it, but if the yellowing were due only to the iron in the paper, hydrochloric acid would effect its removal.

Mr. EDWARDS thought that there was no gelatine in the paper he was using. Mr. HADDON responded that there was always gelatine in the size with which the paper was treated in the manufacture.

Mr. W. E. DEBENHAM concluded from what Mr. Haddon had said that platinum prints to be permanent should be finished in chlorine water.

Mr. WILLIS was unused to speaking in public, but would remark that undoubtedly many of the specimens then on the table had been so acted upon by sulphuretted hydrogen as to present stained whites, but that was not a necessary consequence, for he had applied that test to hundreds of platinum prints without producing any discolouration. His own impression was that iron was not the cause of the discolouration, partly from the colour of the image produced, and partly because the iron salt used in the process was very soluble and was mixed with a much stronger salt, which was dissolved out towards the close of the manipulations; he thought that the stain was produced by a combination of the platinum salt with the size used in the manufacture of the paper. He had tried to secure paper free from gelatine, but his impression was that the yellowed samples of paper before them contained gelatine, which was decomposed under the treatment with chlorine water. Doubtless any increasing discolouration of certain platinum prints with age was due to the presence of iron salts. He had only read one letter in the recent public discussion on the subject of permanency, because he thought that he was better employed in attending to other matters, but he had heard that throughout the discussion there was a most remarkable misuse of terms; it seemed that the whites had discoloured under sulphuretted hydrogen, and this was so stated as to be liable to convey the impression to the minds of most persons that the prints had discoloured. In the dictionary the definition of "printing" was "to imprint," that is to say, to make an impression on paper with something like printing ink; he presumed that the writer of the letter was an old photographer who thought that if the whites went the image would go also, hence his indefinite use of words which he applied to all photographs alike; but if he laid a discoloured silver print alongside a discoloured platinum print he (Mr. Willis) would say, "The former is not in printing ink, but mine is in metallic platinum." He thought that he had heard it stated that he used other salts than those of iron and platinum in the preparation of the paper, but he did not do so, and it was open to any one to test the matter; he distinctly stated that there was no other salt in the paper. Once he used silver and a sulphocyanide toning bath, and four or five years later he found out that he could use lead, with which he knew that oxalate of lead would be formed, and he thought that it might be altered by sulphuretted hydrogen. Lead, in the proportion in which he used it, was positively a benefit rather than otherwise, and some of the prints produced with it were now as pure in the whites as when they were first finished; in fact, Eder says that lead in contact with air is bleached in sunshine. However, he gave up the use of lead in the preparation of platinum paper. He remembered a little thing which occurred in New York relating to the misuse of terms: an artist there, fond of a beautiful young lady, wished to have her likeness ever with him, so went to a platinum type photographer there to have a picture of her printed upon his shirt cuffs. A friend of the artist, who did not believe in the permanency of platinum, betted with him on the question of the durability of the portraits. A few days afterwards he again met the artist. Now the Americans are very particular about the purity of their linen, in spite of which the artist had kept on those cuffs for three days, when they looked faded all over, as the friend remarked the minute he cast his eyes thereupon; the reply was, "Well, they do look bad, and they must be taken to Wah Sing to be washed." This was done, and they came back as white as ever. Although Wah Sing was a terrible man, especially on buttons, he had not succeeded in washing out the platinum prints.

Messrs. C. H. Watkins and T. Watson were elected members of the Association, after which the meeting terminated.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Committee of this Association met at 181, Aldersgate-street, on the 2nd instant. The minutes of the previous meeting were confirmed.

Messrs. L. Blake, A. C. Edwards, B. J. Edwards, Friese Greene, T. J. Dixon, G. A. Garrett, W. England, J. D. England, William Bedford, H. Bedford, Lemere, G. P. Cartland, F. Wilson, T. Edwards, L. Bourquin, W. J. Basket, J. Rice, G. Carroll, W. Jones, W. A. Welford, R. J. Dubbin, W. Young, and Dutton, were enrolled as members of the Association.

The Secretary submitted the cash statement for the past year.

It was decided that the annual general meeting should be held on Monday, the 21st instant, at the above address, at eight o'clock, when it is hoped the members will endeavour to attend and introduce, if possible, new members to the Association.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting of the above was held at the Technical Schools, Broad-street, on the 27th ultimo.—Mr. S. Delicate in the chair.

The minutes of the last meeting having been read and confirmed, the following lady and gentlemen were elected members:—Mrs. Welford, Messrs. J. Chatwin, C. Chinnery, J. R. Curtis, C. Greenwood, W. S. Harding, J. P. R. W. Pumphrey, and J. S. Smithson. Mr. Frank Edwards was nominated for election.

The HON. SECRETARY (Mr. J. H. Pickard) announced that he had received a communication from an anonymous member offering a prize of a standard work on photography for the best lantern slide exhibited at the next meeting, February 10 (lantern exhibition), to be the work of amateurs only; judging to be made by the Lantern Section Committee.

Sundry exhibits were shown, notably panel photographs by J. W. Welford, Gray's direct positive plates by A. Pumphrey, lantern slides and transparencies on Pumphrey's plates from Eastman paper negatives, and silver prints of snow scenes from Morgan & Kidd's paper negatives.

Mr. GODFREY asked: How is it I cannot get detail and density in my snow pictures, either with long or short exposures?

Mr. WELFORD: The negative shown is under developed, and must have been exposed in a strong light. It is always advisable in taking snow scenes to get in as much shadow as possible.

Messrs. B. KARLEEN, E. MIDDLETON, and J. NOCK gave their experiences with snow pictures, and mentioned the fact of the faces of figures taken in the snow coming out black on the prints, which arises from intense light diffusing itself on the plate, causing a kind of halation.

The VICE-PRESIDENT (J. W. Harrison, F.G.S.) then gave his paper on *The Sensitometer*, prefacing his remarks by saying, although it was a good thing for the amateur to thoroughly understand the plates he used, by conquering all knowledge of them by the experience of exposure and developer, which rendered him nearly certain of obtaining good pictures at all times, still it was very useful to the amateur as well as the professional to be able to ascertain with accuracy the rapidity of any fresh make or batch of plates he may happen to come across, and have no previous knowledge of the working of same. The first sensitometer was made by Dean in 1856, and there are several recent ones—including those by Spurge and the celebrated Russian gentleman, L. Warnerke. The latter is the sensitometer by which the bulk of the plate-makers advertise the standard rapidity of their plates. Mr. Harrison then explained most fully this sensitometer (which shows great accuracy and has been the work of Mr. Warnerke for some years of close testing), and afterwards exposed several plates by magnesium light and developed with different developers, showing the certainty of the tell-tale of the instrument.

In the discussion which followed, Mr. PUMPHREY preferred keeping a standard lot of plates which he knew, and then, before using a fresh batch of plates, tested one of the standard and the new ones at the same time, and developing in the same dish.

Mr. MIDDLETON remarked that, of course, Mr. Pumphrey, making his own emulsions, would know whether they were iodide or bromide, because both these, although equal in the camera, would show unequal rapidity under the sensitometer.

The discussion ended in it being resolved that the meeting of February 24 should be set apart for the testing of different makes of plates brought by the members themselves, and developed at that meeting with—pyro and ammonia, by S. Delicate; ferro-oxalate, by J. Nock; washing soda, by J. W. Welford; potash and soda, by J. Iliffe; Beach developer, by J. H. Pickard.

MANCHESTER PHOTOGRAPHIC SOCIETY.

LANTERN SECTION.

THE second popular meeting of the session was held in the large Lecture Hall of the Athenæum on Thursday evening, January 27,—Mr. W. I. Chadwick in the chair.

Views were contributed by the following gentlemen:—Messrs. Gale, Brooks, Wilson, Flincham, Valentine, York; also by the following members of the Society:—Messrs. Greatorex, Coote, Burt, Muth, and Whittaker; in all, three hundred and fifty slides. The views were briefly described by the Hon. Secretary, Mr. Chadwick. A large number of the views were of a very choice description both in composition and manipulation, and well deserved the hearty applause they received from a large audience numbering about seven hundred.

A vote of thanks was accorded to the lanternist, Mr. J. G. Jones, for his services, and the meeting terminated.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE monthly meeting of this Society was held on Tuesday, the 1st instant,—The President in the chair.

After the routine business had been disposed of a report from the Council was read, recommending that a *conversazione* be held during next month, and suggesting March 9 as the date. A resolution was adopted confirming this, the place to be the large room at the Masonic Hall, the members present being earnestly requested to introduce suitable objects, photographic or otherwise.

Mr. A. S. PLATTS rose to remind the members that there was a question box which deserved to be more patronised than hitherto, as, according to his ideas, good, useful discussions often arose by means of its agency.

The Society's lantern being now ready, the PRESIDENT called upon Mr. Atkins to exhibit the competition slides. There were eight competitors—six slides each, which were of excellent quality, and were afterwards arranged in the inclined frame, so as to be judged, against a white paper backing, when the award fell to Mr. T. G. Hibbert for the first place, and Mr. Shields for the second, the voting being by non-competitors present.

Respecting the shape of the masks of these slides, it was noticeable in how many cases the usual cushion and circle had given place to an oblong form (especially when reduced in the camera), by which the whole or most of the original composition had been retained.

The meeting then adjourned.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting of this Society was held at the Greyhound Hotel, Dulwich, on Wednesday evening, February 2,—Mr. Larcombe in the chair.

Mr. W. W. WALKER introduced for discussion *The Properties of Chloride of Silver and its Adaptability for Photographic Printing*. After describing the various chloride of silver papers at present in use, and their method of manufacture, Mr. Walker referred to the recent introduction of colloidal-chloride papers, and pointed out the advantage of finding some suitable substitute for albumen as a coating for silver paper. The introduction of the subject was followed by an animated discussion, in which most of the members joined.

It was decided that the next meeting, of February 16, should be devoted to an exhibition of lantern slides made by the members, and a discussion on the methods of producing lantern transparencies.

PACIFIC COAST AMATEUR PHOTOGRAPHIC ASSOCIATION.

To the lives of most persons come seasons of peculiar satisfaction and days of success, and the same thing occurs in the existence of societies; such was the experience of the above Association on Thursday evening, the 6th ultimo, the date of its regular monthly meeting, when the large attendance at its pleasant rooms showed the general interest felt in its affairs, and put the Directors to thinking how much of an appropriation would have to be made to the Furniture Fund for purchases of additional chairs. The evening was one of the most pleasant of many happy hours spent in the rooms, yet with all the good feeling there was a shadow of sadness, for one chair that was wont to be occupied by one of our most loved members, Mr. Virgil Williams, was vacant. Taken from our midst since our last meeting by a sudden and unexpected death, our Association has been deprived of a genial friend whose kindly counsels and artistic promptings have been most invaluable. Mr. Williams was the Director and moving spirit of our School of Design, and was well known both here and in the city of Boston, where for a while he had his studio, and we doubt that among our artists there was one who was more thoroughly acquainted with the history and technique of art in all schools of its existence. Eloquent and feeling tributes to his memory were paid by Mr. Treat, ably supplemented by Mr. Le Breton.

The feature of the evening was a lecture by Mr. H. S. Bellsmith (who is visiting this Coast in the interests of the Eastman Company) on *The Use of Bromide Paper in Contact Printing and in Enlargements*; and his concise and intelligent remarks, illustrated by numerous specimens of enlargements, in size up to 24x30, were listened to with marked interest, and called forth many inquiries and much admiration.

Mr. BELLSMITH said that he had nowhere in any of the societies he had visited seen such good specimens of bromide work as in the rooms of this Association.

After the active work of the evening, Mr. Le Breton invited those present to visit his luxuriously-furnished rooms in the same building, to test the effect of a new developer (of good feeling); it was of a light straw colour, pleasant to the eye, and was contained in a Japanese bowl on a table, and had to be kept cool with ice, and was measured out with a ladle; a little more or less seemed to make no difference, though more intense feelings were produced by a second application of the same strength. It was voted to be more of a success than the new restrainer (Beer) that the English journals are recommending.

This to show you we are not asleep on the Pacific Coast.

Correspondence.

FEBRUARY MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—PRESENTATION OF BURNT-IN PROOFS ON CHINAWARE.—A CLEARING SOLUTION COMPOSED BY M. BESCH.—AN EXCELLENT ADDITION TO THE CAMERA LEGS OR STAND BY M. BRETON.—HOW TO CURE BLISTERS IN ALBUMENISED PAPER BY A MEMBER.—A DARK-ROOM LANTERN WITH HOT-WATER POT BY M. TONDEUR.—A CAMERA SLIDE BY M. SAURET.—PHOTOGRAPHING A RIFLE BALL MOVING AT A RATE OF 440 METRES PER SECOND.—ON COLOUR ADDED TO GELATINO-BROMIDE OF SILVER EMULSIONS, ISOCHROMATIC, ORTHOCHROMATIC, OR OTHERS.—M. VIDAL ON EASTMAN'S PAPER.

THE Photographic Society of France held their February meeting on Friday evening last, the 4th instant, M. Davanne in the chair.

M. Pinel Peschardiere presented some very fine specimens of burnt-in proofs on chinaware. This gentleman has been experimenting a number of years to obtain a sure and certain means of decorating china, earthenware, &c., and at a cheap rate, by means of photo-lithography.

M. Besch presented a solution composed by himself to prevent fog, or more correctly speaking, to clear negatives from fog. He was informed by the Secretary that many chemicals had that property, and that it was not likely that a secret process would be chosen when so many were already on hand.

M. Breton, an amateur, said he had very often been in great trouble

Piece of grooved wood.

Camera legs with addition.

A A A. Camera legs.
B B B. Grooved wood.
C. Central bolt.

when reproducing pictures in museums to keep his camera stand from slipping on the waxed floors. He had at last completely conquered that

difficulty by a very simple contrivance, "which," said he, "I am very happy to give to the members of the Society, if, peradventure, any of them experience the same difficulty." M. Breton then presented an ordinary three-legged stand. When this was opened a supplementary piece of wood, with a long groove in the middle, was seen attached to each branch by means of a brass hinge; these three pieces of wood were then lowered down and crossed each other exactly in the centre of the leg or stand, that is to say, half-way between the camera and the ground; a bolt was then put into the grooves, and when screwed down held the stand very firmly. By loosening the bolt the three pieces of wood slide one upon the other, so as to give any position whatever to the stand or legs; when the proper position is obtained, the bolt is screwed tight, and the leg or stand cannot slip or move. I try to describe this dodge a little more than necessary, seeing how simple it is, because in my estimation it would be a good addition to every sliding leg in the market, as it doubles its power of resistance.

A member said that he had succeeded admirably in curing blisters on albumenised paper by submerging the prints before toning in the following bath:—

Water	400 parts.
Alum	40 "

A. Body of lantern.
B. Lamp.
C. Red glass door.
D. Hot water pot.
E. Chimney.
F. Handle.

M. Tondeur presented a lantern for the laboratory, to which he had adapted a hot-water apparatus to keep emulsions liquid during the preparation of gelatino-bromide of silver plates. A carpenter's glue-pot would give a good idea of this lantern. It might render service to amateurs and photographers who still prepare their own plates, so I send on a drawing.

M. Sauret exhibited a camera slide, which he certified would not let any rays of light penetrate and spoil the plates. This he obtained by means of a piece of wood, covered with cloth, pushed forward by means of a spring. Here a very sad discussion took place between the inventor and M. Macken-stein as to priority—patriotic sentiments came uppermost, and hard words were said to M. Macken-stein, he being a foreigner.

An amateur of Pesh has been experimenting on the rapidity of gelatino-bromide of silver preparation, and it is said that he has succeeded in photographing the ball from a rifle during the trajectory which it described on leaving the muzzle of the rifle. The experiment was made with the Werndl rifle. It appears that the plate reproduced the ball when moving at a velocity of 440 metres per second. The ball is represented as surrounded by air taking an hyperbolic form.

A discussion took place upon isochromatic preparations. M. Tailfer claimed the honour for France, his establishment, he said, being the first to prepare them.

This subject, I think, ought to be cleared up at last—so many are in the field at present as the inventors, &c. An international jury might be nominated to study the subject, hear evidence if necessary—either written or verbal—give judgment, and so honour may be given to whom honour is due. My opinion coincides with that of many: that no patent whatever can prevent a colour to be added to an emulsion, as this has been done to my knowledge since 1877. At that period I made a great number of gelatino-bromide of silver plates, the emulsion of which was tinted with eosine or some other colouring matter. These plates were bespoken by M. Ducos du Hauron; he supplied the colouring substance. I am surprised that an English house should cease adding a colour to their emulsion on account of a patent. That Herr Vogel, of Berlin, prosecutes any one taking the name of orthochromatic plates, or M. Tailfer, of Paris, does the same in the defence of his title, well and good, but to go further encroaches upon public liberty, and this must be tolerated no longer.

M. Vidal gave a description to the Society of his experiments on Eastman's paper. He took an over-intense enlargement and plunged it into a solution of bichloride of copper, twelve per cent.; after well washing the paper, from which the image had disappeared, it was laid in a feeble bath of sulphocyanide of potassium, then in the developing bath; the image was renewed, and had obtained its proper degree of intensity.

44, Rue des Moines, Paris.

PROF. E. STEBBING.

A HOME FOR THE PHOTOGRAPHIC SOCIETY.

To the EDITORS.

GENTLEMEN,—During a recent meeting of a scientific society at Burlington House, I was forcibly struck by the advantage in every way it would be to the Photographic Society, and to photography generally, to possess a house of its own, or a set of rooms at least; and now I see, by your paper of last week, that the worthy President of the Photographic Society has broached the subject. I hope the matter will not be allowed to drop. I should say the Society meets as often, and its meetings are as

well attended, as those of the societies which are so handsomely provided for in Burlington House. Photography, it seems to me, has equal claims to such recognition, for is not its use required in almost every pursuit, whether scientific or not? An establishment of its own would give the Society an impetus and enlarge its sphere of usefulness.—I am, yours, &c.,
Beckenham, February 7, 1887. J. C. S.

BURNLEY EXHIBITION.

To the Editors.

GENTLEMEN,—Will you permit me, through your columns, on behalf of the Burnley and District Amateur Photographic Society, to thank most cordially those gentlemen who so kindly and courteously responded to my appeal for exhibits for our Exhibition which has recently closed? It was very gratifying to receive so many contributions from both amateur and professional photographers from all parts of the kingdom, as it exhibited what a great amount of camaraderie exists amongst the brethren of the art, as our Society must have been almost unknown to them. I trust all received their exhibits on return in such a state as will warrant my being able to make a like appeal without fear of refusal.—I am, yours, &c.,
7, Bank Hall-terrace, Burnley. WILLIAM SUTCLIFFE, Hon. Sec.

PHOTOGRAPHY IN INDIA.

To the Editors.

GENTLEMEN,—The old Bengal Photographic Society of former years has probably figured in these pages as the leading Society in the East, but owing to the difficulties of getting apparatus, &c., and the want of energy on the part of the members as a body, it eventually died a natural death.

Thanks, however, to modern facilities and the increased number of amateurs, a proposal was made in March, 1886, to revive the Society under the title of the Photographic Society of India. The difficulties of collecting a working Committee out here are far greater than at home, chiefly owing to the effect of the climate, which, excepting the very short period of three months, is commonly called "purgatory." However, by dint of exertion the list of members has increased, and is not far short of a hundred members just now.

Our general meetings have been well attended, and the latest arrival from home is anxiously looked to for an account of the latest inventions. Shutters of all sorts have had their share of attention, and some of the latest patterns, such as the "Grimston," are considered wonderful for ingenuity, though the ordinary drop shutter can boast of the best results in difficult work as far as the Society is concerned. Though we may be behind the times, we wish to follow on as fast as possible, and to this end we want samples of the rapid printing papers which appear to be so much used in England. Messrs. Eastman's papers have found their way here and are very highly thought of, though a trial of keeping them through last rains proved too severe. Of course the papers I refer to were not sealed up in tin, which would have effectually preserved them. While on this subject, I would suggest that all papers sent to India should be sealed up in small quantities, for dealers here must clear out old stock, and after a few months of damp there is great risk in purchasing on the spot. The platinotype process is worked by many, but for the greater portion of the year it is almost impossible to get satisfactory results, owing to damp. Paper negatives have been carefully tried and are well thought of, but the slight extra trouble necessitated in working goes much against them in a country where one has so little inclination to exert oneself. Roller slides are by no means uncommon here, but we are all troubled with the want of an index on the outside of the case. Generally speaking, the number of amateurs who do their own silver printing is very small, but professional assistance has been most cordially given to members.

An exhibition, open to all, was proposed last year, but the funds of the Society being an important point, it has been decided to postpone it till January, 1888, when we hope to gather together a goodly collection of pictures from all parts of the world. Further information on this point will be sent out in a few months.

As Secretary to the Society, I beg to invite photographic dealers to forward us lists of novelties, and as before stated we are very anxious to get out samples of the new printing processes. Unfortunately, as yet, we have no home agent to refer to, and we scarcely know where to apply for samples. Dealers here will not order them out on chance, and until the Society has given them a trial they will still remain unknown in Calcutta.

Of our prospects we are still uncertain; the Society has lived a year and flourishes, and under the able presidency of Colonel Waterhouse we have every reason to look forward to a long life. Before long we propose to exchange Oriental views with Societies at home, and as soon as we can run to a Society lantern we shall be pleased to participate in the friendly exchange of slides which has been arranged between England and America.

I have only further to say that we shall be very glad to have advice regarding the proposed exhibition, and obliged for any assistance from our distant friends.—I am, yours, &c., JOHN S. GLANSTONE,

Hon. Secretary of the Photographic Society of India.

8, Clive-street, Calcutta, January 11, 1887.

HALATION.

To the Editors.

GENTLEMEN,—Some people seem to have very vague notions as to the cause of so-called halation which sometimes appears in paper negatives. The interior of a church, say, is taken on an embossed glass plate, and in the resulting negative it will be found that, though the details of the windows are all sharply and exactly depicted, still the whole of each window is enveloped in a fog caused by the reflection of the light from the back surface of the glass. This defect may be overcome by reducing the fogged portion by any of the usual methods; but I have found that by far the best plan is to give the windows a further printing under a vignette. Now if a sensitive film on a paper support be exposed on the same subject it will be found that the outlines of the leading and other dark portions are quite destroyed, in some cases even the leading being entirely obliterated, the surrounding high lights being merged together into one mass. Now this is caused by the diffusion or spreading of the light through the white substance of the paper, and though more local than halation in a glass negative, is far more destructive in its effects, as nothing short of a pencil can restore the lost details. I have never noticed anything of the sort excepting in the case of very long exposures.—I am, yours, &c., H. A. LEWIS.

Binsted, Arundel, February 7, 1887.

YELLOW STAINS ON NEGATIVES.

To the Editors.

GENTLEMEN,—I can hardly agree with your correspondent, "J. G. R.," respecting the advantage of the yellow stain in negatives. It certainly does not much matter where it is but slight, but where it is of a brownish yellow colour, like mine was, the time taken in getting a print may be reckoned by days.

It may be of some service to your readers to know that this stain may, to a considerable extent, be removed by a solution of oxalic acid. Having used a strong solution for removing stains upon my hands caused when developing, it occurred to me that a weak solution might remove the colour from the negatives. I tried it, and found that it discharged the denser part of the colour, leaving the negatives a pale yellow tint. As might be expected, it produces frilling, and must be used with caution.—I am, yours, &c., G. SMITH.

Dudley, February 8, 1887.

DEFECTIVE MOUNTS.

To the Editors.

GENTLEMEN,—I take the liberty of sending you a sample of mounting board taken from a stock we have just lately had delivered. I was very much surprised to notice that when damped in the process of mounting photographs on them such a smell of sour paste was evolved as to make it almost unbearable in the workroom. On further examination I found them to be very acid. The boards I usually use have no such smell, and fancying something was wrong I complained to the firm who supplied them. The reply they give still more astonishes me. They say, "The makers state the boards are perfectly good, and have never before had a complaint, though we have made boards of the same quality for over thirty years."

Now, Gentlemen, so much has of late been said and written about the fading of photographs, that I am inclined to think the fading of silver prints may to a great extent be accounted for by boards such as I now complain of finding their way into the market. I cannot understand how silver prints coming into contact with such an acid substance can stand for any time. I should be much indebted to you for your opinion, and if you consider it would be safe to mount silver prints on boards such as I send you the sample of.—I am, yours, &c., JOHN STUART.

120, Buchanan-street, Glasgow, February 1, 1887.

[The paste employed in making the board has probably been sour. Such would be fatal for silver prints.—EDS.]

Exchange Column.

* * * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange luxograph lamp for whole-plate group lens.—Address, BERTIN STUDIO, 440, Old Kent-road.

I will give a cottage barrel-organ, eight tunes, or a good head-rest, for Lancaster's 12 x 10 view lens.—Address, W. SAUNDERS, Dickleburgh, Scole.

Wanted to exchange, gem camera and six lenses for studio camera, stand, or interior background.—Address, A. J. B., 17, Hindon-street, Fimlico.

Will exchange pair of buffalo horns, mounted (six feet), for half-plate camera (square), with latest improvement, double slides, and good view or portrait lens. Cash differences.—Address, HUDSON, Godmanchester, Hunts.

will exchange a Ross' No. 3 C.-D.-V. lens for a rapid symmetrical, difference in value adjusted; also a posing chair with four backs for a portable camera and double slides.—Address, W. T. WHETTER, Photographer, Villiers-road, Bristol.

Quarter-plate Starnes's camera, with Newton's 5×4 rapid rectilinear lens; will exchange it for pair of Ross' or Dallmeyer's quick-acting stereoscopic lenses or whole-plate rectilinear.—Address, BONA VISTA, care of Myles, Uddingston, Lanarkshire.

Will exchange portable 10×8 camera, with double and single slide, by Meagher, for 10×8 or whole-plate universal studio camera and slides; also another 10×8 camera and slide, two quarter-plate portrait lenses, and tripod stand, for studio accessories or backgrounds.—Address, WALTER DAWSON, Waring Green, Brighouse.

Will exchange Seavey's backgrounds for others by same artist; also garden seat, fireplace, rockwork, cottage, Eclipse shutter, and a Ross' cabinet portrait lens. Wanted, a 12×10 camera, three slides; also quarter or half-plate ditto, 12×10 wide-angle lens, enlarging lantern, or Haddon Hall steps, &c.—Address, F. WHALEY, Photographer, Lincoln.

Chemical balance by Oertling, modern make, fourteen-inch beam, agate planes and knife edges throughout, with double rider apparatus, specific gravity pan, and all adjustments, in handsome mahogany case with counterpoised sliding front, two drawers, and lock and key; in perfect condition and adjustment; cost £18 18s. Will exchange for tricycle by good maker; central-gear Premier or cripper form preferred.—Address, CHEMIST, 2, York-street, Covent Garden, W.C.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

J. C. S.—The Ross' portable symmetrical of six inches focus will serve the purpose.

J. T.—The incandescent burner referred to is not yet an article of commerce in this country.

W. C. B.—There is no restriction upon the employment of two plates side by side in a dark slide.

CORRIST.—Stop out everything in the group by means of Chinese white, except the one figure, of course.

FOCUS.—We have not yet been able to ascertain the precise cost, but it will probably be from 1s. 6d. to 3s.

F. W.—Before purchasing any other lenses try a component of one of the "rapids" as a single lens, using an aperture of about $f/8$.

W. EMPSALL.—If you state the circumstances under which the dark room has become damp we will then be better able to indicate a remedy.

O. X.—The mottling on the plates arises from the emulsion being imperfectly washed, hence the haloid salts have crystallised out as the plates dried.

A. B.—The electric light is now employed at all demonstrations in the Society of Arts, and it is that belonging to the Society. Your letter will be submitted to the officer in charge.

E. D.—1. Possibly the lack of density is due to the negatives being under exposed. If this be not the cause use more pyro in the developer.—2. If the two lenses be employed with apertures of the same ratios the exposures will be practically the same.

C. J. E.—This matter can only be determined by actual comparative experiment. If the compound lens does not define to the edges without a small stop, it may probably give a flare-spot in the centre. If it does so, this indicates that a preference should be given to the single lens.

CARBON writes: "I have some cabinet negatives I wish to print in carbon (single transfer); is there any method by which I can get reversed negatives without getting a transparency of each?"—Yes, reversed negatives can be made direct from the originals by the powder process; or they may, with some brands of dry plates, be made by taking advantage of the reversing action of light obtained by a long exposure.

W. B. WOOD.—The rays should fall upon the graphoscope lens as nearly in a parallel direction as possible; hence it must be placed a considerable distance from the condensing lenses, or, to speak more correctly, it must be made one of the elements of the condensers, although far apart from them. Possibly it will prove more satisfactory if you try the system in which a ground-glass backing for the negative is recommended.

POISONS writes: "Kindly inform me, through your 'Answers to Correspondents,' if I make myself liable to be proceeded against under the Poisons Act for selling chemicals to amateur photographers?"—If the chemicals be any of the poisons mentioned in the Schedule, such as cyanide of potassium, bichloride of mercury, &c., of course our correspondent renders himself liable to a penalty. If the chemicals supplied are not poisons no harm is done.

A. B. CLARKE writes: "I have been using lately the developing formula described on page 141 of this year's ALMANAC, but I find such a tendency to frilling that I never found with the ammonia developer; am still using the same make of plates. Do you think the soda solution too strong is the cause of the frilling?"—It is quite possible that the frilling proceeds from the cause suggested. See an article on the subject by Mr. H. W. Gridley on page 200 of the ALMANAC.

J. T. ANDERTON says: "I have a quantity of cabinet carbon prints which I wish to mount, but as they are thicker and much more glossy than silver prints, I fear the ordinary starch mountant will not be strong enough unless the prints are damped, in which case the enamel-like surface will be spoiled. Can you tell me how to proceed so that their beauty may remain unimpaired?"—The prints need not be wetted if thick starch paste be used. Or, in place of starch, a thin solution of glue may be employed.

GEORGIUS puts the following questions: "1. My toning bath gets rather black although I filter it. Is there any way of making it clear? Is this discolouration harmful in any way?—2. How long should a toning bath last if strengthened from time to time with gold and acetate of soda?—3. What do you recommend for keeping the smooth bar of a burnisher in order?"—

1. The discolouration arises from some of the gold becoming reduced. When out of use the solution should be kept in the dark. The discolouration will do no harm except that so much gold is wasted.—2. For many months.—3. A perfectly flat oilstone.

J. WHYTE puts the following queries: "1. Where can I be supplied with photo-lithographic transfer paper, i.e., paper coated with gelatine but not sensitised with bichromate?—2. Does any firm in London prepare for the trade a heavy tissue suited for Woodbury reliefs that may be moulded from or electro deposited upon for photo-typographic blocks, and please name the firm?"—In reply: 1. Photo-lithographic transfer paper is supplied by Mr. E. Liesegang, Düsseldorf, Germany.—2. Those who work the Woodbury and analogous processes make their own tissue. Perhaps the Autotype Company can supply a suitable article.

A. H. D. writes: "I have some oil paintings to photograph, and large prints are required, would you suggest, 1. That I take them on quarter-plates and enlarge on Eastman's paper, or can you propose a better plan?—2. Is no special treatment of the paintings required in order to secure good results?—3. Do you recommend the use of orthochromatic plates for this purpose?"—In reply: 1. The best plan will be to copy the paintings direct the size required and then to print from the negatives.—2. All will depend upon the paintings themselves; sometimes they require special treatment, but not always. A little glycerine rubbed over the surface will often enable better copies to be obtained.—3. Certainly.—4. We never recommend any particular maker's goods. That is strictly against our rule.

A. B. writes: "Will you kindly say what sizing compound is used in preparing the paper for photo-lithographic transfers, and whether it is applied before coating with gelatine or after development of the inked print? The reason of our question is because of the tendency of our prints to slip on the stone while under pressure, through want of tackiness, the original sizing of the paper being washed out during development. Could you also tell us if a paper prepared for this purpose is to be found in the market?"—Different photo-lithographers have different methods of preparing their transfer paper. Usually it is a fine paper coated with gelatine only; sometimes albumenised paper is used. The slipping, we imagine, is due to want of skill in the operation of transferring. Better get a few lessons from a practical lithographer in transferring. See reply to "J. Whyte."

ORNAMENT writes: "A friend of mine is getting up a little ornamental article for the Jubilee year, and the ornamentation consists of an emblematical portrait of the Queen surrounded by some important events of her reign. The engraver has taken his likeness (only) from a copyright photograph, the other portions are original. Will you tell me if this is an infringement of the Copyright Act? The article would in no way interfere with the sale of the photograph, being altogether a distinct thing."—If the engraving be made from a copyright photograph, of course it is an infringement, and the pirate renders himself liable to the penalties, namely, ten pounds for every copy issued as well as forfeiture of the plate. It matters not whether the pirated copies will interfere with the sale of the originals or not. If the owner of the copyright chooses to take proceedings he can recover the penalties.

THE next meeting of the North London Photographic Society will be held in Myddelton Hall, Upper-street, on Tuesday next, the 15th instant. Subject: *The Characteristics of the Photographic Lenses in Daily Use*, by J. Traill Taylor. All are invited.

PHOTOGRAPHIC CLUB, Anderton's Hotel, Fleet-street, E.C.—The subject for discussion at the next meeting of this Club, Wednesday, February 16, 1887, will be adjourned discussion on *The Art Treatment of Photography*, with a demonstration by Mr. Norman Macbeth, R.S.A.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday next a demonstration will be given by Mr. J. Hubert on the toning of collodion-chloride prints and the application of the process to the making of lantern transparencies and the reproduction of negatives.

*** We have again unfortunately been compelled to leave over some "Exchanges," Mr. Berkeley's communication, and several other important articles, but hope to have space for their insertion next week.

No. 1398. VOL. XXXIV.—FEBRUARY 18, 1887.

DRYING AND MOUNTING GELATINO-CHLORIDE PRINTS.

ATTENTION has been called to the fact that no mention was made in our recent articles on *Gelatino-Chloride Paper*, of the drying and mounting of the finished prints; and as these operations differ sufficiently from the usual practice with albumenised paper to raise rather serious difficulties in the way of beginners, we have pleasure in supplementing our previous remarks by the following hints.

In the course of the articles referred to it was pointed out that, owing to the nature of the sensitive surface of the gelatino-chloride paper, it was impossible to employ warm solutions or to dry the prints by heat; in addition to this, owing to the more or less adhesive character of the surface, the use of blotting pads for hastening the drying is *contra* indicated. These circumstances may at first sight raise a vision of difficulties which do not really exist.

We will suppose the prints have passed through the toning and fixing baths and have been thoroughly washed, the next operation—and it is a most important one—is to immerse them in the “hardening” bath of ordinary or chrome alum. This not only helps to protect the surface of the finished and mounted print from subsequent injury, but it also greatly facilitates the remaining operations of drying, mounting, enamelling, rolling, &c., by rendering the surface less adhesive while wet, and harder and more like albumen when dry. An immersion of five minutes in a saturated solution of common alum, followed by a rinse for a minute or two in clean water, suffices for most purposes; but if an extremely hard and perfectly insoluble surface be required we prefer to employ chrome alum of the strength of five grains to the ounce, followed as before by a final washing. In using chrome alum care should be taken that the solution is not strong enough nor the immersion sufficiently prolonged to stain or degrade the lights of the picture.

Having arrived at this stage, the prints are ready for drying by the method usually recommended, namely, squeegeeing on to glass or ebonite; or they may be dried like ordinary prints by simply hanging, in which case, of course, the surface will not possess so much glaze as in the former. In order to produce the high gloss a sheet of plate glass is most thoroughly cleaned with a paste of tripoli or whiting and ammonia, and then carefully polished with a silk handkerchief. It is then prepared for the “transfer” process by a further polish with a weak solution of wax in perfectly pure benzole, or with powdered talc. If the former be employed, a little of the solution should be poured on to the plate, quickly rubbed over the whole surface, and finally gently but thoroughly polished with a silk handkerchief, until no apparent trace of wax is left. This is

an operation which requires some experience, as if too much wax be left on the plate the print will strip with an uneven surface, while if the polishing be too *violently* performed and the wax completely removed, it will not strip at all, but remain firmly adhesive to the glass.

Most operators now prefer to use powdered talc which is easier of application, and will bear any amount of polishing off. The plates should be allowed to rest for some time after polishing and before use, in order to allow the electrical excitement to subside; they are then carefully dusted with a soft brush or clean silk handkerchief, and are then ready for use.

The only requisites in the next operation are a porcelain dish of suitable size, a squeegee, and some clean water. A sheet of indiarubber cloth a little larger than the prints to be operated upon will be found an additional convenience, and costs but little; the squeegee may be purchased in various sizes at most photographic dealers, and is also inexpensive, or it may be made by screwing a strip of sheet indiarubber, about an eighth of an inch thick, between two pieces of wood to stiffen it, leaving about a quarter of an inch of its width projecting. A smooth edge may be given to it by working or grinding it after mounting upon a flat stone with a little emery or fine sand.

All being ready for mounting, let one of the prepared glasses be laid, polished side uppermost, in the dish of perfectly clean cold water; the print is then plunged face downwards into the water, and one edge being brought into contact with the corresponding edge of the glass plate, and the two clamped together with the thumb and forefinger of each hand, they are slowly drawn from the dish in perfect and intimate adhesion. The plate with its attached print is then laid upon a flat surface, the indiarubber cloth placed over it and held firmly by the edge with the left hand, whilst with the right the squeegee is passed, at first gently, and afterwards more firmly, over the whole surface, so as to press out as much as possible of the water contained in the body of the print, and between it and the glass. Unless the glass be much larger than the print, the rubber cloth should be held firmly against the table and clear of the glass, but in any case the fingers of the left hand must not rest upon the print. The mounted print may now be reared up in a cool place to become dry.

We have hitherto spoken only of glass for the purpose of mounting for drying, but other materials may be used, and are preferred by some; glass, however, gives the finest surface, if that be an object. Where a slightly lower glaze will suffice or is preferred, thin sheet ebonite or ferrotype plates may be substituted, the preliminary treatment being exactly similar to that given to glass. Sheet xylonite or celluloid has been

recommended, but this we have never tried, though we have no doubt as to its efficacy, and it is susceptible of a very high polish. These substances, especially ebonite, permit the stripping of the dried print more easily and with greater safety than glass, for which reason alone they are worth a trial.

IN *La Nature* of the 12th instant will be found an engraving of a remarkable photograph—a view taken from a distance of over one hundred miles from the objects by Messrs. Émile Courvoisier and Charles Humbert. These gentlemen had often, fruitlessly, endeavoured to obtain such a view; but at last success crowned their efforts, and the negative they obtained, if it be anything like the engraving, must be looked upon as a feat of photography. They had often desired to possess a panoramic view of the Alps, which should be more exact than the usual lithographs, and more than once they tried photographing in full daylight, but not a trace of the brilliantly-illuminated mountains could be perceived; sky and mountains were merged into one flat tint. It then occurred to them to take a view a little before sunrise, and, after several trials, they succeeded in obtaining a satisfactory negative, with an exposure of fifty or sixty seconds. The actual distances of the elevations depicted are—Jungfrau one hundred and five, and Weisshorn one hundred and thirty kilometres. We think that their claim to have produced a view such as had never before been done will be allowed by all.

AN electric battery always ready for use, and capable, with a few cells, of giving sufficient current for the illumination of a good glow-lamp, is still a *desideratum*. There are cells, like the Leclanché, always ready for use, but requiring an immense number to produce a small light, and cells like the bichromate, which give an excellent light with a small battery only but which rapidly run out, and there are all kinds between the two. We would draw the attention of our readers who, for photo-micrographic or dark-room purposes require such a lamp, to an article in the *Chemical News* over the signature, H. N. Warren, R.A. He has invented a battery, which he states he has found to be the most powerful yet examined. Taking a cell of the bichromate pattern, he replaces the usual exciting liquid by a slightly acidified strong solution of chloride of iron, with a layer of bromine at the bottom of the cell. Ferric chloride being very soluble, a much stronger solution at the outset may be obtained; and it is kept up to strength, as the zinc is acted upon, by reason of the recuperating action of the bromine, which, as the ferrous chloride forms, reconverts it into the original ferric form. The bromine itself, as it becomes absorbed in this process, may be brought back to its original condition by adding a little bleaching powder solution. Mr. Warren states that the strength of the battery is only slightly reduced after three hours' continuous action, and that after a little rest it recovers its original power. If all that is thus claimed should turn out to be as stated, such a battery ought almost to revolutionise electric lighting by battery on a small scale.

WE are again promised cheap sodium, which, as our readers are aware, means cheap magnesium, aluminium, &c., and this time with a show of certainty. It is announced that Mr. Castner, of Belyedere-road, Lambeth, will give a full account of the process before the Society of Chemical Industry on the fifth of next month. He uses a compound of iron and pitch coked together as the reducing agent, the operation being performed in large steel crucibles. It is stated that a quantity of caustic soda costing about fourpence is capable of giving, with the expenditure of a shilling, one pound of metallic sodium, now worth about eight or nine shillings. If this news prove to be true, magnesium should be producible at such a price as to render its use in the studio a matter of the most trivial expense, while the introduction of cheap aluminium would revolutionise the mounting of lenses and many other photographic requirements. We have already described on previous occasions the Cowles method of producing the last-named metal and its alloys by means of the electrical furnace, which is now in full work in America, and we learn that a still larger machine of a similar character is being made for use in this country, the combined engines for which will represent a total of about three thousand horse-power.

A *SUITABLE finale* to the transport and safe receipt of the great lenses for the Lick telescope is found in a description which we read of the last resting-place of the munificent founder of the telescope and observatory. His body was formally transferred to the custody of the trustees on a recent Saturday evening, the coffin remaining in a room in the observatory during the night. On Sunday an address was read by the President of the observatory, and the coffin was lowered into a cavity in the foundation pier of the great telescope and permanently built in.

WITH regard to Schott's optical glass, which is now attracting so much attention, we note that our contemporary, the *English Mechanic*, is giving a complete list of the various kinds made, with a translation of the descriptions, in German, which head each column. The list will, no doubt, be extremely useful to those amateurs who attempt lens grinding; but this is an operation attempted by few photographic workers, though for microscopic and telescopic objective construction there are many amateurs of first-class ability in this country. As bearing upon our previous remarks on the subject, we may observe that some of the glass tabulated is described as suitable to be used only where there is no dampness nor contact with water. Some of it, further, is "not very hard," other termed "soft," while other, still, cannot be made free from bubbles.

IN *Nature* last week will be found an elaborate article on "Instantaneous Shutters" for photographic use. The whole subject is well thought out, and the possible practicable efficiency of shutters constructed upon different principles is mathematically calculated. Circular and rectilinear apertures are both treated of, and the general conclusions arrived at are summarised at the end of the article. They are as follows:—(1), That there is room for great improvement in the photographic efficiency of shutters; (2), that all the ordinary kinds shake the camera when the exposure is rapid; but that (3), for comparatively long exposure, say more than one-tenth of a second, almost any kind of shutter will do when the camera is mounted on a stand; and (4), that for cameras which are to be held in the hand, in order to secure fine definition, the shutters must be dynamically balanced or exceedingly light."

ACCESSORIES OF THE LANTERN.

CHAPTER III.—SCREENS.

SCREENS may be divided into two classes, translucent and reflecting. Translucent screens were formerly in general use, the sheet being placed between the lantern and the audience, whereas now, in nineteen cases out of twenty, the lantern is situated on the same side of the screen as the audience, so that the image is seen by reflected light only.

Translucent screens usually consist of linen, rendered semi-transparent by a temporary wetting. In screens of this class above ten feet square there is usually a dark line across the pictures during an exhibition, which is caused by the necessary joining of the fabric, as it is not manufactured wider than ten feet without seam. This objectionable line may be reduced to a minimum by joining with "carpet stitch," by which any overlapping of the edges is avoided. Another defect of the wetted screens is the brilliant spot of light which is caused by the rays from the lantern passing straight through the screen without diffusion, owing to the minute interstices in the linen; a third fault is a great loss of light; a fourth, the limited space usually available behind the screen renders the use of very short focus lenses imperative, thus producing inferior definition. These matters have caused the plan of showing through the screen to go quite out of fashion, especially as there is now nothing to be gained by the concealment of the lantern, which was necessary for the phantasmagoria illusions. A translucent screen for small discs is easily made by pasting a large sheet of tissue or tracing paper over a child's hoop or other framework. This screen will not require wetting, as the material is already sufficiently transparent.

Reflecting screens may be made quite opaque; a smooth-plastered wall which has been newly whitewashed makes a first-class reflecting surface, and one that is difficult to surpass. It is obviously not a

convenient screen to travel about with, but where lantern exhibitions are constantly being given in one place, and the hall is suitable, it is perhaps the best plan that can be devised. Such a screen will reflect about thirty per cent. more light than an ordinary linen sheet, and will show the colours of slides in their full beauty. The difference of quality between pictures shown on a perfect surface and those exhibited on an ordinary screen, especially if the latter is slightly yellow in tint, is greater than might be supposed; there is a beauty and freshness about the former which is not observed in the latter.

Paper screens are excellent when new. A cotton sheet may be pasted over with white paper, and fitted with a roller and strong lath, like a school map. It will hang at first very flat, though if any sharp creases are produced they are troublesome to remove, hence such a screen requires careful usage, and should not exceed ten feet square in size. When soiled they are rendered as good as new by repapering. If a screen of this class is made over ten feet in length, it is not handy to travel about with, as the luggage vans on the passenger trains do not always admit a greater length than this. Where a large screen is wanted for one particular hall, a paper-covered one answers admirably. There is such a screen, about twenty feet square, arranged to roll up like a theatrical drop-scene in the main hall of a school at Burley-in-Wharfedale. This, by-the-way, is the model school of the late Right Hon. W. E. Forster, in whose presence about four years ago I had the pleasure of exhibiting and describing lantern views at two of the annual "breaks-up." Mr. Forster seemed then in excellent health and spirits, and determined that he and others should enjoy themselves; he was hearty in his manner, and very popular in the school and district. The large screen referred to was let down in a few seconds, and saved a good deal of time that might otherwise have been expended in stretching a linen sheet in the usual way.

A screen about six feet square may be made without any pasting by a sheet of stout white drawing paper, which is sold of a considerable width at the artists' material dealers; it should be fitted with roller and lath so that it may be rolled up without creases.

The size of a screen is an important consideration, and depends more upon the dimensions of the hall than on the intensity of the light. If a screen is too large for the hall, the audience will be unable to appreciate the beauty of a picture shown thereon as a whole—their attention will be directed to the details only, and in such a case the defects of the picture—dust, spots, and brush marks—will be painfully apparent. If the screen is too small, the picture, being viewed by the bulk of the audience at too great a distance, appears insignificant. I have, in my own practice, found it a good rule to have the diameter of the disc equal to one-fourth of the length of the hall, thus: a fifteen-foot disc for a hall sixty feet long, a twenty-foot disc for a hall eighty feet long, and so on. The screen being at one end of the hall, the bulk of the audience will then view the pictures at a distance about equal to twice their diameter; they are then near enough to see every detail of the pictures if they are properly illuminated, while they are not close enough to discern clearly the microscopic defects which are present in nearly every slide.

It is instructive to note the different impressions produced on two persons by a lantern exhibition on a large scale, the one sitting near the screen and the other at a fair distance from it. I have known the former to be completely disgusted, while the latter was filled with admiration. A similar instance seems to have occurred lately at the Society of Arts Hall on January 6, where slides were shown by the electric light on a large screen. Mr. George Smith, seeing the pictures from too near a standpoint, becomes painfully conscious of the imperfections of the pictures, and straightway puts the blame on the light, and goes on to assert that the oil light is superior to the electric and even the limelight for projection! No doubt an arc light of over 1000 candles is more powerful than is necessary for an eighteen-foot disc, as a limelight of 600 candles would be amply sufficient; but if Mr. Smith had been a little further away from the screen I think he would not have expressed himself in such a manner. I am afraid if his customers were only allowed to use the oil light when displaying the excellent slides he manufactures that his business would suffer.

There are many halls in which the ceilings are whitewashed and the side walls very light coloured. In such a case the light proceeding from the image on the screen is reflected back, so as to render the room very light, and hence the picture may look misty. If there is

no ready means for partially protecting the screen from the light thus thrown back on it, it is advisable to adopt a small sized disc. The diffused light in the room will be the same in amount as before, but the superior brilliancy of the image on the smaller scale will to a large extent overpower the fogging action.

The position of a screen being usually at the extreme end of a hall, it should be raised sufficiently high to enable those who are at the opposite end of the room to see the lower part of the pictures; hence the lower edge of the sheet should be about four feet above the floor line. In the case of large halls, the height may be six feet, but it is not desirable to dislocate the necks of half the audience by making the pictures too high. The screen should, if possible, lean slightly forward at the top, so as to be "square" with a line extending from the lantern to the centre of the disc. By this means distortion of the pictures will be avoided, and the audience will see the pictures to the best advantage.

ALBERT WM. SCOTT.

ECHOES FROM THE SOCIETIES.

THAT was a rather curious experience of Mr. F. York's reported at a meeting of the London and Provincial Photographic Association, but it is scarcely susceptible of any useful explanation until the experiment has been repeated under clearly established conditions. Two negatives exposed at the same time were kept, before development, one in the dark slide, the other in paper, and the latter was stated to have been "accelerated" by contact with the paper. Two points, however, strike me. Nothing is said about the two plates having been accurately timed as to exposure, and it is possible that a slight difference in that respect, unnoticed perhaps at the time, may account for the effect; or the plates themselves, though from the same batch of emulsion, might, from a variety of causes, have differed slightly in sensitiveness. On the other hand, setting this view on one side, and granting the exposure and sensitiveness to have been identical in each case, the plate exposed more freely to the atmosphere in the dark slide than its companion wrapped in paper may have been "slowed." The final result would be the same, but with the same difference experienced by the Irishman who, having ordered a pair of boots, one of which was to be slightly larger than the other, complained subsequently that the shoemaker had misconstrued his instructions and made one *smaller* than the other. If Mr. York will repeat the experiment with the same kind of paper, making *one* exposure in the camera, and cutting the plate in halves, then covering a portion of one half with paper, and enclosing it between clean glass plates before wrapping it up, the result upon development will give us a definite point from which to start.

A few weeks ago I had to make allusion to orthochromatic photography, which still appears to absorb a great deal of interest, scarcely a meeting of importance being reported without some reference to the new development in our negative processes. But decidedly the simplest and most novel process is that of M. Theophil D'Haoûw, of Gand, described by Mr. W. H. Harrison at the London and Provincial Photographic Association. The process exhibits undoubted ingenuity, but in obtaining the results claimed I fancy M. D'Haoûw must draw largely on an imagination which in the first inception of the method has given evidence of a vast capacity for stretching.

We are told that M. D'Haoûw employs neither eosine nor yellow glass, but merely waits until twilight or until "the blue colours in the object found little blue incindent light to throw off," hence a good orthochromatic effect is obtained. It is of course well known that at the close of the day the blue rays exist in comparatively small proportion to the yellow; it is also true that even the yellow or luminous rays are present in much smaller quantity than at midday. Any beginner in photography will be able to tell M. D'Haoûw that it is easy with a long exposure to photograph a blue object late in the evening when it is impossible to do anything with yellow, because the photographic action fades out of the yellow end of the spectrum far more rapidly as the light wanes than out of the blue. In true orthochromatic processes the sensitiveness of the plate to the yellow rays is increased while the blue sensitiveness is little, if at all, lowered. In M. D'Haoûw's method the blue rays are cut off or got rid of until they have little power to act, and without attempting in any way to

increase the sensitiveness of the plate to the already feeble yellow rays these are still more reduced in power, with the result, I should guess, that a diametrically opposite result to that euphemistically described as "a good orthochromatic scale" would be obtained. Certainly *quod non erat faciendum*.

When the general tendency in all quarters is to do away with the use of yellow screens in consequence of the lengthened exposures they necessitate, I can scarcely imagine that any one would seriously look at such a method even supposing it to be theoretically accurate. With all our great increase of sensitiveness in the past few years for many purposes, we are open yet to a still further and vast increase, notably in printing processes. A few days ago I particularly wanted a print from a certain negative for a special purpose. The negative was not a dense one by any means, though slightly yellow in the shadows; but after an exposure in the open air for the whole day the darkest shadows were sufficiently "out" to render visible a large insensitive patch hitherto unnoticed, which rendered it necessary to start afresh. If our experimentalists in orthochromatic photography would turn their attention to printing processes I venture to predict that the blessings showered on their heads (when successful) would, during the months from October to February, far outnumber all that go to negative processes during the whole year.

Before leaving "orthochromography," let me suggest a subject for dabblers in the new art to try their hands or lenses or plates upon. Let us see what effect they can produce in copying a print on ferrous-prussiate paper. If such a print be viewed through yellow glass or, better still, with the sun shining on it, through ruby, the blue colour is transformed to black, and the picture has the effect of a platinotype, with this difference, that the colour is of a velvety richness only seen in platinotypes from the very best and most suitable negatives. A similar result should be rendered with an orthochromatic plate.

The Glossop Dale Photographic Society has set a good example to others, and done itself honour at the same time that it has performed an act of kindness to a class of poor creatures whose lines are cast in the roughest of places. At last month's meeting it was resolved "That the Society give a lantern entertainment to the inmates of the Glossop Workhouse, subject to the approval of the Board of Guardians," which approval would scarcely be withheld, I imagine, unless the Glossop Guardians are made of harder stuff than even guardians are usually supposed to consist of. Bravo, Glossop Dale! Yours is a far better way of amusing yourselves than half a dozen "smoking concerts" or entertainments to your "swell" friends, who don't thank you for being "bored," and can afford to pay for being amused if they want it. Your audience can't afford to pay, and will not be bored.

I notice a revival of the movement in favour of new sizes for lantern slides, this time at Dundee. Mr. Geddes proposes to make a sort of panoramic slide on a plate of the old stereoscopic size, which is to be passed slowly through the lantern after the style of the old travelling "panorama." Whether the plan will find favour remains to be seen, but I expect there will be some difficulty experienced in securing subjects entirely suited to the style.

MONITOR.

PHOSPHORESCENT TABLETS.

USERS of the "Standard" sensitometer would do well to take note of Captain Abney's remarks on the reliability, or rather *non*-reliability, of the phosphorescent tablet as a guide. It has been long well known that for purposes of comparison between sensitive films of varying composition the adopted sensitometer is valueless, and it has further been doubted whether any two samples of the phosphorescent material possess identical qualities; but it would scarcely have been suspected that so old a hand as Captain Abney could have been led astray to the extent that seems apparent from his statement that a tablet in his possession five years old gives a much stronger light than another only two years old.

This difference might arise from two causes: from greater luminosity of the sample of sulphide of calcium originally used for the older tablet, or from the more rapid deterioration of the newer one either before or after spreading the phosphorescent material on glass. As regards the first-named cause, there is of course no doubt as to its

existence, though it may be presumed in the case in question that Captain Abney tested the raw material before using it. The vagaries of sulphide of calcium are well known, not only in the matter of intensity of luminosity, but also in colour, the latter varying from violet through nearly all the shades of the spectrum to red. It is therefore possible that a brilliantly luminous sample may from its colour be of less photographic value than another whose apparent brightness is less. Here lies the great difficulty in establishing a phosphorescent standard, and if the truth be told it seems possible only to employ for purposes of comparison those tablets which have been made from one particular sample of the sulphide and under identical conditions.

Not only do different samples vary in their initial luminosity, but the diversity in their powers of retaining that brightness unimpaired is equally great. Further than this, the conditions under which they exist in tablet form, that is, after admixture with paraffine wax, affect the quality and uniformity of the surface to almost as great an extent. Thus a small quantity of the sulphide I purchased some years ago entirely lost its phosphorescent properties in the course of a few months, though preserved in a stoppered bottle and tied over with a double thickness of thin gutta-percha tissue such as is used for surgical purposes. A tablet of it spread, *à la Warnerke*, upon glass retained its pristine brightness for a very considerable time until accidentally broken. On the other hand, a larger quantity which has been kept in a jar simply tied over with sheet indiarubber does not appear to have varied appreciably during the four or five years it has been in my possession, though tablets made from it at various times have varied to such an extent in their powers of retaining luminosity that two, which I tried side by side under sensitometer conditions upon pieces cut from the same sensitive plate, gave respectively the numbers 22 and 31.

The temperature employed in making the melted mixture of paraffine and sulphide no doubt exerts some influence upon not only the immediate luminosity of the tablet but also upon its stability, while the thickness of the layer spread upon the glass has an even greater influence in enabling the plate to retain its brightness. I find the best plan to be to apply a very thick coating, using equal weights of wax and sulphide, and the lowest temperature possible to keep the mixture liquid. Such a mixture made in quantity is poured on to a warmed plate of larger size than the tablet required, to the depth of three-sixteenths of an inch, and the whole placed for a few minutes upon a levelled and warmed surface of metal or plate glass. This keeps the mixture liquid, and permits the sulphide to sink to the surface of the glass plate, leaving the upper portion consisting of nearly pure paraffine as a protection against atmospheric influences. When quite cold and hard the back of the tablet may be scraped level, the plate cut to the required size and backed with a second piece of glass, the whole being bound together after the style of a lantern slide, when the result will be as permanent as anything of the sort can well be. The melting point of paraffine varies in good samples from 130° to 136° Fahr., and this will do little harm to the sulphide.

ERNEST GRAMAM.

OXYGEN AND LIMELIGHT MATTERS.

You have already noticed the information given by a correspondent in the *English Mechanic*—Mr. E. Holland—as to the advisability of mixing salt with the chlorate and manganese mixture in making oxygen; and as I tried his method the next time I was making gas after his communication, I am very glad to be able to report that it is really a valuable "wrinkle." Lest it be forgotten, let me repeat that you take by weight—

Chlorate potash	8 parts.
Manganese oxide	2 "
Common salt	1½ "

It is to be observed, also, that the chlorate is *powdered* when using this mixture—not used in crystals as usual. I did not find that it answered *quite* so quickly to any variation in the heat as stated—"instantly" Mr. Holland wrote—but as the gas-burner I use was turned up or down, the flow of gas did respond to it very quickly indeed. I was longer than usual in filling my bag the first time, simply because I was all the while trying experiments on this point, and was quite satis-

fied about it; no one need fear a "rush" who adopts this recipe. There is also a slight advantage in the quantity of gas evolved, for I could have burst the bag or blown off a cap with the same weight of chlorate usually taken to fill it. This action is rather peculiar; for although it is often stated that you get more gas by powdering the chlorate, under ordinary treatment the reverse is the case, and you get less. With the salt you do get more, and the comfort in steady production is very great. We all owe a debt to Mr. Holland for his modification.

A word as to wear of bags. I have already shown how damp and impurity in the gas may be absolutely avoided. But in one point my experience, which is, however, far more limited than Mr. Scott's, differs from his, perhaps because it is more limited. Also, I try to do no work at all in the summer with my lantern. But, with this qualification, I myself dread the cold weather far the most, and most of my leakages have occurred after it. It appears to make the indiarubber more brittle, and as the bag is used and then refilled, the rubber seems to crack or give way in the creases or folds. Vulcanised tubing always "perishes" if exposed long to cold, and probably it is the same with bags. At all events, I have always found bags give way first at the folds, and especially the "corner" fold on each side; and a repair at these spots helps it along for a further period. While, however, pretty sure about this for the time during which I do use gas, I have no doubt whatever as to really hot weather being all that Mr. Scott says.

I planned my own boards differently from any which he has described—disliking cords or straps, or anything of the sort. I prefer a board *between* the two bags, when no cords or straps are needed. As no strain comes upon this middle board, it need not exceed half an inch in thickness; and my top and bottom boards are only a "full" five-eighths, proper cross-pieces giving the strength at the ends. These boards measure 42 x 34, and bear four half-hundredweights easily, but are not heavy. The legs are also different, there being no base-frame at all, but legs hinged to the front end just like those of a housemaid's pair of steps, while to the other end is hinged a wooden "stretcher," such as is also used instead of a cord on some of these steps. This stretcher rests on the cross-piece joining the two legs, which has sticking up from it two iron studs, over which drop holes in the stretcher. This holds all perfectly rigid and safe; and then, when the gas is about half used, the stretcher is lifted off the studs by the toe of one boot, which also (the front end being a little lifted meanwhile) sets back the stretcher and legs flat against the under side, and lets the whole down flat on the ground. A carpenter's price for the whole set was 17s. 6d., and they are nearly as portable as "skeletons" of the same large size. Legs and stretcher, being hinged to the under cross-pieces, are really attached about five inches from the ends.

A correspondent not long ago gave an altogether wrong impression of the relative cost of bags and bottles in use. To begin with, it will be seen that I should knock off a lot from the cost of pressure boards; and on the other hand, the valves of bottles need pretty constant care to keep from leakage. We may, however, take the cost of the plant at, roughly, the same in both cases, and limes will of course be the same. But it is in the *working* cost the difference comes, and I agree with a more recent correspondent, that it is this which is prohibitory where cost is any object. Suppose we want 10 feet of each gas, the cost of making which was over-estimated. Really, it amounts to rather over 2 pounds chlorate at 8d., and $\frac{1}{2}$ pound manganese at 2d.—say 1s. 6d. If I use bottles, I must pay for 10 feet at 8d., 6s. 8d.; and 10 feet of house gas at 6d., 5s.—in all 11s. 8d., just 10s. 2d. more. Well, I cannot afford it. Like your second correspondent on this point, once let us have the oxygen at 4d., and house gas at 3d. (the latter practically costs the pumping and wear and tear alone), and I will never make any more. But I much doubt if this will ever be the case, and must not be understood as implying that the present charges are at all excessive. I am told that even they only "pay" during the regular season, and do not pay except when in full swing. The fact is, the plant is very expensive, and rapidly deteriorates when not in use. At present, I am told, the gas is pumped in the first instance into large pressure gasometers or reservoirs of immense strength and very costly, and the small bottles are filled from these, and not direct from the pumps as formerly. When this was done, so much heat was generated (precisely as in a "live-syringe" experiment) as to be dangerous, and the explosion at the Royal Institution was believed to be due to this

cause: hence the new plan, which also keeps the pumps at work for some time continuously, which is necessary to profit. If this is true, I fear any serious reduction in price is hardly possible. This is the real obstacle to the adoption of bottles, where mixed jets are used; and all the argument in the world will not get over it till the solid figures are changed.

By the way, I should like to know one point about the new regulator from any who have used it. Will it keep the pressure down *when the jet is turned off*, so that it may be turned off when desired and the consumption stopped? That is the real test; if it will do this it must be all that can be desired.

Perhaps I may be allowed to state, in reference to the jet alluded to by Mr. Pringle recently, as made for him by Messrs. Newton, that (except as regards his own additions) it may be regarded as my jet, or what has been arrived at by my own experiments. All that I required for these—each little modification arrived at step by step—was carried out by Messrs. Newton, and subsequently tested with them; and the nipple was bent backwards and forwards many times at various angles, before that he describes was adopted. The nipple, also, is the external shape we found to give the best light, and the large and ample mixing chamber is of special importance, and allows every operator to introduce any kind of packing he desires; though the jet is usually supplied with only one piece of gauze, and I myself generally use none at all. The lime-turning motion is also that described by me last winter. I must say, however, that I find it easy enough to burn big holes or pits in the lime even at this angle, and believe pitting depends more on the power used and the lime than on mere angle. Mr. Pringle's own addition will be very convenient for me. Hitherto I have attained the same object in my own experimental work by using a dissolving tap, and corking up one set of apertures. It will be seen how this operates in the same manner for a single lantern, which is chiefly in use; but Mr. Pringle's addition on the jet itself will save fixing a dissolver, and be more convenient to me in many ways.

LEWIS WRIGHT.

A CRITICISM OF THE PLATINOTYPE DISCUSSION.

Few persons have done more to benefit photography in its historical aspects than Mr. W. Willis, in that he has effected so much in the way of making photographs permanent, instead of but ephemeral phantoms serving a temporary purpose. In society, the encouragement of the almost lost art of miniature painting is now reviving, probably because of the experience imparted by the deplorable appearance of likenesses in old albums, so that the phrase is gradually coming into use, "Only a photograph;" in short, it is high time that professional photographers bestirred themselves to start a new fashion in photographic portraiture, and endeavoured to convince the public that the new pictures are permanent, consequently that the poor man can have his family portrait gallery as well as the rich one.

In view of the importance of this one of the several comparatively permanent processes, perhaps a few critical remarks about the recent meeting of the London and Provincial Photographic Association in relation to platinum printing may not be out of place.

Döbereiner, many years before the announcement of the Talbotype and Daguerreotype processes, discovered that a solution containing an oxalate and bichloride of platinum would throw down metallic platinum when exposed to sunlight. This early discovery of the first principles of one of the platinotype processes, has not, so far as I know, been heretofore emphasised in the photographic literature of this country. I discovered about Döbereiner's achievement in the course of researches in the British Museum Library, but afterwards found out that Dr. Eder was aware of it, for he gives a few lines to the circumstance in his great standard work on photography now in course of publication in parts. In the English translation of the admirable little book on *Platinotype*, by Captain Pizzighelli and Baron A. Hubl, the opening sentence relates to the frequently quoted experiment by Sir John Herschel, announced to the British Association at Oxford in 1832, of treating bichloride of platinum with excess of lime water and exposing it to light, whereby chloroplatinate of lime was thrown down; the authors then give some experiments by Döbereiner, made public in 1834. Apparently they are not aware that Döbereiner was in the field before Sir John Herschel, and that, too, with closer approximation to a working photographic process. On page seven they state that Döbereiner found out that a solution of platonic chloride is decomposed by light in the presence of oxalic

well as of some other organic acids, but they give no date. On page twenty-three they state that Döbereiner was the first to observe the reduction of some of the organic ferric salts by light, and did so in 1831, but here they say nothing about the reduction of platinum. Sir John Herschel has done splendid work for photography, but in this particular instance the book should have opened with the discovery of Döbereiner, and not with the later one of Sir John Herschel. In early times Döbereiner also reduced chloroplatinite of potassium by light in the presence of potassic hydrate and alcohol. Döbereiner's discovery gives the early history of the platinum process a highly respectable and not generally known antiquity.

The question was raised at the recent meeting, whether the presence of gelatine in the paper, and a combination of it with a salt of platinum, would cause the whites of a print to darken under the influence of sulphuretted hydrogen. Mr. Willis says that he avoids gelatine, and as a substratum uses starch. In relation to this matter Captain Pizzighelli and Baron Hubl say that starch as a substratum gives platinum prints of a sepia colour, whilst a gelatine substratum gives pure blacks, bluish in the half tones; with their commercial papers they use a substratum of gelatine. The rest of the process they employ is virtually the same as Willis's, so on the point just mentioned there is a discrepancy between the statements of the highest practical authorities on the platinum process, which discrepancy requires clearing up. In the sizing of the paper itself as turned out by the manufacturers, Captain Pizzighelli and Baron Hubl intentionally or unintentionally avoid gelatine, their paper being "sized" at the mills with "resin," if the expression may be allowed. They say, "The paper we use is half sized (resin-size)." They avoid papers containing ultramarine, because it turns yellow under the influence of hydrochloric acid. That several platinum salts exercise a coagulating power upon certain colloids is known, and Sir Humphry Davy was, so far as my literary researches on the subject go, the first to make known the fact, for in a paper of his read before the Royal Society in days before he had been admitted a fellow thereof, he alleges sulphate of platinum to be the best known test for "jelly." He dried the precipitate so produced at a temperature of 212° Fahr., then analysed the product and found it to consist of 56.11 parts of oxide of platinum, 20.02 of sulphuric acid, and 23.87 of "gelatine" and water. I have found some of the salts of platinum to slowly coagulate collodion in a closed bottle to a tough, springy residue. As regards the other portion of the problem mooted at the meeting, it should be known that paper manufacturers sometimes use at least two kinds of sizing, and that once the *Société d'Encouragement* of Paris gave the following recipe as the best one it knew, and in which it will be noticed there is no gelatine:—100 kilos. dry paper stuff; 12 kilos. starch; 1 kilo. resin, previously dissolved in 500 grammes carbonate of soda. There are several other published formulae for resinous paper-sizes if any one cares to hunt them up, but the worst of the matter, from a photographic point of view, is that, as a general rule, all kinds of refuse and inferior samples of material are considered good enough for use in the manufacture of the substance known as paper, which substance at the present time is acknowledged everywhere to be a chemical product, rather than an output of guaranteed material consisting chiefly of the cellulose of the cotton plant.

To these who are working the platinum process of commerce, I would recommend a trial of hot instead of cold water, acidulated with hydrochloric acid as in the usual clearing baths, and to take care to give each print its full time in those baths, because I have found attention to these two points to have much influence in clearing the residual iron out of prints in various processes not connected with platinum, in which a salt of iron is used. It would be well to ascertain whether old platinum paper has more tendency to retain iron than paper freshly prepared. Furthermore, it would be well to get on record the influence, if any, of the soaking of the prints in alkaline solutions for two or three days, as such solutions exercise special solvent power upon some of the subsalts of platinum, the object being that an effective platinum printing process shall stand before the world without fear and without reproach.

One thing which has tended for years to keep back the adoption of platinum printing in this country, is the feeble blacks of nearly all the platinum prints exhibited until recently at public exhibitions; the prints usually had a weak, washed-out look. The first platinum pictures with rich deep shadows seen by me, were exhibited at the 1885 Exhibition of the Photographic Society by a Cambridge photographic portraitist, and the prints exhibited quite recently by Mr. F. M. Edwards leave nothing more to be desired in that respect. Yet we have Captain Abney publicly complaining but a few weeks ago that he could not get deep blacks with the paper, and questioning whether his sample of the paper had been too thinly coated. Are these variations in the results of operators due to their own

method of manipulation, or due to variations in the issued samples of the commercial paper, whose proprietors certainly cannot be supposed to wish to do anything which shall raise prejudice in the public mind against platinotype prints as compared with prints of silver upon albumen? M. Léon Vidal does not wish for a strong glaze upon platinum prints, but suggests that they would look richer if treated with a solution of shellac in borax, dried, and rolled: There may be something to be said for this with prints of *carte* size, and the elegance and good taste of the French in artistic matters carry weight, but I think that except with prints of less than half-plate size, if taken upon a *smooth* sample of platinotype paper, there would be a loss of artistic beauty were any more glaze given; Mr. J. B. B. Wellington's platinotype pictures practically illustrate what I mean.

W. H. HARRISON.

PHOTOGRAPHIC LENSES.*

I SHALL now show, projected on the screen, a considerable variety of photographic objectives, and make a few observations on each in turn. First of all I remark there are two ways by which a plano-convex or a meniscus lens can be achromatised. A biconvex crown may be wedded to a plano-concave flint, or a concavo-convex flint to a plano-convex crown. If the meniscus is to be very deep in its external form its components may be a plano-convex crown cemented to a plano-concave flint, although opticians generally prefer that the contact surfaces be curved, on account of the greater command it gives them for the correction.

The earliest form of objective was the plano-convex or slightly curved meniscus. For reasons already given it has a diaphragm, or stop, in front. In order that it should work with a larger aperture the late Grubb reversed the relative positions of flint and crown, by which he was enabled to bring the diaphragm rather closer to the lens. Still later the late Dallmeyer modified it by placing the flint between two crowns, for which further advantages were claimed. By recent improvements in the selection of glass and curvature, this old objective (which in all its various forms is still much employed) is now made with such a large fixed diaphragm as to render it capable of being employed in portraiture. This, of course, is owing to the minimising of the spherical aberration. While admirable in other respects it is unsuitable for copying or for architectural purposes on account of its refracting the lateral rays in a greater proportion than the central ones. This distortion does not show near the middle of a picture, but becomes apparent when the included angle is moderately wide. From the nature of its construction it cannot supply the condition of orthographic projection, namely, that a ray shall emerge in a direction parallel to that at which it enters. To this end the ray would have to pass through the optical centre, which in such a lens cannot be done.

The Petzval portrait lens consists of a nearly plano-convex achromatised lens in front, with a double convex posterior lens at the other end of the tube. This latter is composed of a biconvex crown and a concavo-convex of flint glass, the inner curves not being concentric, and the two are separated to a slight extent. This back combination fulfils a two-fold function; it shortens the focus and thus intensifies the illumination, and as it possesses a large degree of negative spherical aberration it counteracts the positive aberration of the front lens, and thus with a large aperture it brings rays to a sharp focus over a field quite large enough for single portraits. Some years ago Dallmeyer introduced a modification of the back lens, reversing the relative position of its elements, as Grubb had done with the landscape lens, the requisite negative aberration being obtained, as in the Petzval back, by the inner surfaces not being concentric. This form of back lens lends itself to the lowering of definition, when such is desired, as in the case of large faces in which the rugosities of the skin are not always desirable.

An American optician, Morrison, makes some of his portrait lenses (especially those for taking a large standing figure with full aperture) with an uncemented front lens and a Petzval back, the inner curves of the front lens being non-concentric.

The most recently introduced lens of the portrait class owes its inception to Steinheil, and is constructed on lines quite different from all others. The front is a cemented positive combination, and consists of a convex crown and a concave flint. The back combination is composed of a biconcave flint and a biconvex crown, these being separated to some considerable extent. Each combination exhibits chromatic and spherical aberration to a large extent, but in an opposite sense, so that the two combinations correct each other.

He has also imported the same idea in the construction of a land-

* Concluded from page 84.

scape lens possessing greater power, and in which the back crown element is of unusual thickness, and is cemented to the flint. It is claimed for this construction of objective that the marginal definition is of superior class, and that astigmatism has been eliminated. In the landscape form the lenses are set so closely together as barely to permit a diaphragm to be inserted between them. The name "antiplanat" is applied to them.

One or other of the lenses above described is employed in everyday portraiture in the studio. It is that class by which the greatest angular aperture can be secured.

I have said that Petzval made the calculations of two objectives. The second, which lay in abeyance till 1857, was designated the orthoscopic lens, from a property claimed for it of giving rectilinear projection, but which subsequent investigation proved unfounded. Although it has been supplanted by others it is a useful lens, and gives good definition over a moderately large field with a large aperture. The front lens is the usual front achromatic of the portrait combination, with a smaller negative lens or dialytic placed a short distance behind. This dialytic lens is composed of a meniscus flint and a biconvex crown. This lens is useful when one desires to take a larger image than the extension of his camera permits, as its focal centre is anterior to the front combination.

Out of the orthoscopic lens were evolved others of different forms which were free from the imperfection to which I have alluded, the most popular of these being the triple achromatic lens composed of three cemented compounds, the front and back being plano-convex or slightly meniscus in form with an achromatic negative lens between them by which the field was rendered flat.

The triple combination lends itself in an admirable manner to the production of what I may term a universal lens, by which I mean adaptability or adjustability of focus. Some years ago I constructed a lens of this class in which a very wide slit was cut right through the mount in the position occupied by the concave lens. In this was fitted a sliding piece of brass pierced with four holes, in each of which was set an achromatised lens of a negative power. Notches on the slide ensured the lenses being quite central. The combination to which this system is attached is composed of two nearly plano-convex lenses, which when used alone do not give a flat field. By inserting the slide the influence of either of the four concave lenses is to lengthen the focus and flatten the field. The foci I obtain by this slide are respectively seven, nine, twelve, and fifteen inches. When not in use this slide packs away in a neat little pocket case, six inches long by one and a half inches wide, and half an inch deep. Of the advantage of being able to secure more or less subject on a plate, without having to unscrew or change the lenses, I need not speak.

Wide-angle non-distorting objectives are a great power in the hands of a photographer who knows how to use them aright. Among the earliest of these was the American globe lens, so termed from the outer surfaces forming part of a globe or sphere. From the example now shown, it will be observed that each lens (the combination is symmetrical) is formed of a meniscus crown with the shorter radius from the optical centre, cemented to a concavo-convex flint. The construction of this lens favoured the formation of a flare spot or ghost in the centre of the picture, which would have disappeared had the maker departed from his globular idea and brought the lenses a little closer together.

In 1864 Ross took the matter up and brought out a doublet free from the shortcomings of the globe. It was unsymmetrical in internal structure, being composed of a biconvex and a biconcave cemented front, and a concavo-convex and meniscus back combination. The lighter element, as you see, is to the outside of the front and the denser element to the outside of the back. Soon after this Zentmayer introduced a ratio lens, one in which the front and back elements were of dissimilar diameter and focus, the diaphragm being placed in the optical not the mechanical centre. The objective was composed of two single or non-achromatised meniscus lenses of very deep curvature, and included a very wide angle. A feature by which it was distinguished consisted in a series of lenses of different foci all screwing into one mount under such circumstances as to retain the diaphragm in the correct position for all of them. This was improved upon by Dallmeyer, who made a wide-angle rectilinear lens in which the lenses are each achromatised.

A wide-angle lens much used in America, made by Morrison, consists of a very deep achromatic front lens and a single or non-achromatic crown meniscus as a back lens, of rather flatter form than the front. This, presumably owing to slight over correction of the front, aided by the well-known adaptability of the deep meniscus form, defines sharply over an extended field. There are other forms of wide-angle lenses, but I have spoken of most of those of a representative character.

We now come to a class of lenses so similar to each other in construction that one diagram will suffice to illustrate all. They are those to which the prefix "rapid" has been in many cases applied, in addition to a nomenclature so stupendous as would indicate the ransacking of almost every living and dead language to supply.

In 1866 Steinheil introduced a lens formed of two cemented combinations, adapted for covering a moderately large field with an aperture of a seventh of its focus. Instead of forming it of flint and crown glass, which would not admit of such an aperture being employed, he used two kinds of flint glass, one possessing a higher index of refraction and dispersion than the other. From their wide aperture they were designated *aplanats*.

Numerous makers took the matter up, some by servile imitation, others by making departures more or less slight. This objective, which is more or less good according to the skill of the optician by whom it is made, is, for all-round work, one of the greatest possible value, for in a fairly good light it acts as a portrait and group lens; it is sufficiently rapid to enable the photographer to secure horses, even railway trains, in motion; it is orthoscopic, or rectilinear, hence can be employed for copying, and provided care in this respect has been bestowed upon its construction, it serves as a landscape lens, in giving no ghost or flare. But it is unfortunate that some makers, in their efforts to render it otherwise perfect, do not realise the importance of providing against the defect named. The lenses are separated so far as to hit a happy medium between flatness of field and astigmatism, and this is not unfrequently attended with flare. I have invariably found that this defect may be cured by bringing the lenses a little closer together in the mount. Even so little as the width of two threads of the screw has proved to dissipate the flare spot, which in many cases consists of an image of the diaphragm which has a relation of conjugate focus to the back lens when internal reflections form a factor in its production, although it is sometimes occasioned by reflections from the front lens. Some makers of this lens have departed from strict symmetry, and claim that a more satisfactory result is obtained by having the back lens a little shorter in focus than the front.

But to revert to Steinheil: he did not rest satisfied with the introduction of the lens just spoken of, but made another having less angular aperture and greater angular covering power. It is formed of material similar to the other, the lenses are very thick, and are set very close together. Owing to their small diameter, lenses constructed on this principle are singularly portable, considering their great covering power, and one of our leading optical firms in London has made a speciality of extremely portable lenses of construction akin to that projected on the screen, in which the mounts of all are of similar diameter and fit into one flange.

Morrison, of America, makes lenses for which properties analogous to those described are claimed. He employs ordinary optical flint and crown glass, and corrects by making his crown lenses plano-convex, united to biconcave flints, the contact surfaces of which are but very slightly curved. One peculiarity of this form is that definition fulfilling the requirements of artists is obtained by lenses having shallow curves, and being made of ordinary flint and crown, they are less liable to discolouration by light or abrasion by friction than if composed of dense flint. The lens shown on the screen also serves to illustrate the configuration of the American lenscope objective, which, being made of large dimensions and long focus, is mainly intended for large direct heads.

There are several other topics than those touched on which belong to photographic lenses. Among these are diffusion of focus, so called, or depth of definition as produced by spherical aberration, and by the use of a diaphragm; astigmatism: conjugate foci; lenses for special purposes, such as projection, enlarging, detective and panoramic cameras; the shape and use of the diaphragm and its proper position; the nature and cure of distortion; single or unachromatised lenses; the testing of lenses for the various aberrations, and, lastly, their grinding, mounting, and treatment. But it would be impossible to get all these overtaken in one paper.

J. TRAILL TAYLOR.

DEVELOPMENT OF EASTMAN BROMIDE PRINTS.

[A Communication to the Camera Club.]

CERTAIN remarks that have lately reached me, by channels public and private, caused me to devote some time and a little careful experiment to the use of the bromide paper sold largely, in America and here, by the Eastman Company. I confine my remarks, as I confined my experiments, to that paper, but I would like it to be clearly understood that, for all I know, other bromide papers may come under precisely the same rules, may have the very same defects and the very same excellencies, as the Eastman paper. I have never used any

of the other bromide papers since certain improvements, of which I read and hear, have been made, and I have no right and no intention to say a word, good or bad, about any paper except the Eastman, and so I trust I shall not be taken up wrongly by any one who uses other papers.

A member of this Club made, at a meeting, the remark that "thin, flat" negatives were required, or were the best for printing on bromide paper, by contact, as I understand him to mean. In terms very plain, but I hope, not brusque, I expressed my opposition to his statement; but soon after, remembering that my experience of papers, other than Eastman's, was not of very recent date, I was inclined to repent my haste, more especially when a skilled office-bearer of this Club told me by letter that some of our best workers disagreed with me on the point at issue. I felt confident enough of my rectitude regarding Eastman's paper, "but," thought I, "Eastman's paper is not every paper, and I may be wrong about other papers." Then, in an editorial in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, I came across the following sentence, plain enough and inclusive enough, to put me on my feet again:—"In development printing on bromide paper, the best results will accrue from the employment of a tolerably vigorous, though harmonious, negative." (*THE BRITISH JOURNAL OF PHOTOGRAPHY*, December 24, 1886.) Now, we all know that a "tolerably vigorous" negative cannot be synonymous with a "thin," much less a "flat" negative. So that on the whole I gave up my idea of smoothing down my assertion, and my opinion remains as it was, that thin, flat negatives are *not* the best for printing on bromide paper of any kind with which I am, or ever was, acquainted. That a decent print can be made on bromide paper from a thin, flat negative I will allow—in fact, I propose to attempt to prove it; but to those intending to print on bromide paper, my advice is to make your negatives anything you like *except* thin and flat.

I send for your inspection a few negatives, picked out of the few not packed away, as being representatives of what I venture to call various-characteristic negatives. I did not choose them as likely to give me good prints; I did not intend to make good prints. I chose them as being of very different kinds. You will find one a mere ghost, another outrageously dense; two others of the same view—one over dense, the other too thin in about the same proportion. Except one, the views are all more or less snow scenes, one being a very awkward subject, a dark foreground *in shadow*, with a background of snowy hills. Two of them are unprintable on albumen without "dodging" or specially prepared paper; the others are all more or less printable, but not one of them makes a really good albumen print, though several print passably.

I send also twelve consecutive prints on bromide paper; these I made straight ahead. I send all I made, good, bad, and indifferent, and in printing them I used no dodges of any kind; I put no paper nor colouring material, nor did I mask any part of any negative. One I held to the gas at a slope; there is a slight appearance of masking, but you will find it due to the negative. Apparently there was a cloud on the hill, though I did not notice it.

The exposures of these prints vary considerably, as you will gather from the appended notes. Mr. Burton will tell you the proportion between ten seconds to gas at sixteen inches, and ten seconds to daylight; it is a pretty large figure. I included in my trials a couple of exposures in the daylight enlarging camera, but it was impossible to gather any lesson from these, as the light was very bad and constantly changing; in fact, a heavy fall of snow came on in the middle of my second exposure. My developer also varied in strength. I began each time by making a solution of six of Eastman's potash-oxalate solution to one of his iron, and I added each time half a grain of ammonium bromide to each ounce of the ferrous-oxalate solution. But, as you will observe, I added water sometimes, and a very great difference it makes in the result. On two occasions I added a drop or two of my hypo bath, and in one, which I have purposely left untrimmed, you will see, on the left top corner, the red fog, due to an over-dose of hypo, or rather to pouring on too frequently at that place a developer containing an over-dose of this very debatable accelerator. While I am on this subject, may I suggest that it would be very instructive to members if failures were more frequently shown? More may be learned from one failure, if the operations have been carefully noted, than from one hundred perfect results. My chief regret is that my negatives are nearly all snow scenes. These are so little familiar to us that it is more difficult to arrive at sure conclusions; but, as I said before, I had only a few negatives at hand, and they were either snow scenes or else too good for my purpose.

But the conclusions I arrived at were perfectly confirmatory of what I had gathered from less accurate observation, and I will venture to state some of them.

First. With bromide paper prints can be produced, without any dodging, from negatives practically unprintable by any other process. I would like to see a decent print by any process whatever, except bromide paper, from the dense negative of Haddon Hall that I exhibit, and yet, instead of over hardness, which is the character of the negative, my print is, if anything, the very opposite. And, except by gelatino-chloride paper, I do not think any decent print could be produced from the negative already referred to (a foreground in shadow, with a background of snowy hills), and yet my print is the very opposite in character to the negative, for while the negative is, for the most part, a spectre, the print is distinctly hard. I do not think any amount of dodging with other processes would make good prints of these two, yet you will see that with slight variation in exposure I might have made these prints *perfect*, while dodging is as easy with bromide-paper printing as any other process. For example, if I had any great object in making a perfect print from the spectral negative, I would mask or colour the weak part. The other, the dense negative, requires nothing at all beyond a very long exposure. Printing this on albumen, to make anything like a decent print, I have had to sun the paper down to an alarming extent, and the negative is altogether too hard, even for platinotype.

Secondly. I concluded that there are certain rules which can be laid down for the guidance of workers with this paper, and some of these rules I may point out.

(A.) Full exposure means softness. (B.) Short exposure means contrast. (C.) Strong development means brilliance. (D.) Weak development means softness. (E.) Bromide means vigour.

Now, if we have a good medium negative to print on bromide paper we can do pretty much as we like with it. We may make a hard contrasted print by a short exposure and a strong development, or we may make a "soft" print by full exposure and weak developer. A very hard negative can be made, in printing, as soft as desired by a long exposure to a bright white light and a weak developer. A very "thin, flat" negative may be made into a print as plucky as we wish by a short exposure and a strong developer. Bromide has a very powerful action in the developer; if the image comes up too quickly, an extra dose of bromide, applied instantly, may make the print brilliant, even to hardness. But, I think, if the image does not begin to appear with full-strength developer in about thirty seconds, or forty at the most, that print will not be of much use. When the developer is weakened with water, the image appears more slowly and gains density more slowly; sometimes a minute elapses before any appearance of image. If the development is *too* slow a certain grain appears in the paper; that print, as a rule, is not worth much.

It is very important to acidify the paper after development and before washing. I use citric acid; water with much lime is bad. Always alum after fixing. My prints sent are not alumed; I had no time. You can give the prints a glaze by squeegeeing to talced glass, or to ebonite sheets, or you can leave them with their natural surface, smooth or rough.

And the bromide prints are "Permanent"—as permanent as any purely photographic printing process we have.

ANDREW PRINGLE.

PHOTOGRAPHIC PORTRAITURE.

[A Communication to the Edinburgh Photographic Society.]

As the painter must ever be beholden to his brush and other mechanical aids to the expression of his genius, so must the photographer make intelligent use of his appliances in order to the production of his best efforts. As portraits may be painted or produced by other means than those usually employed, so may photographic portraits be produced without a studio, but to the professional man the studio is as necessary in the one case as in the other. Amid all changes certain requirements remain, and the studio is one of these. Let me say a word about it. All manner of construction and situation is to be found, and probably advocates for every variety we can think of; but while many are compelled to do with less than they could wish, or a different situation than they could desire, a very general inclination will be found in favour of a north light. My own preference is decidedly towards a north or north-east aspect. My studio is seven feet six inches in height at the side, rising from that at an angle of forty-five degrees. This I consider a good serviceable height. It will be found that a high roof lessens the effective control of the light by the operator, without which just so much more difficult and uncertain will it be to obtain the most satisfactory results. The construction of a studio, apart from its relation to the principal light, has not, I think, very much effect one way or other on the work produced in it, unless it is of a most awkward and inconvenient description. It must be a very faulty studio indeed in which good work

cannot be done, provided there be on the part of the operator the necessary knowledge of the requirements of any particular case, and how to meet them by skilful adjustments, and what I might call artistic tact.

In the matter of lighting the subject, one man's work is apt to partake of a certain uniformity of character, arising from his constantly working under the same, or nearly the same, conditions. A very common error many operators fall into is to set every sitter on the same spot and endeavour to direct the light they judge most suitable on that spot, instead of trying the effect of different points, where they may be placed in relation to the main light; in fact, bringing "the mountain" to Mahomet, instead of Mahomet to the mountain. Where the facilities for doing this are very limited, or where it cannot be done at all, there is no more to be said, and the best must be done with what is available.

Where we have to deal with strong contrasts, such as white hair and high complexion, or white and black draperies, the subject will be most effectively treated by being made to face the light; where the conditions are reversed, an opposite treatment, according to the particular demands of the case, must be resorted to. The matter can only be referred to in general terms. A skilful operator will determine what to do when the subject comes into his hands, and especially when he sees the sitter in the light which falls just about where he is to be taken.

If good lighting necessitates considerable study and knowledge of effects, posing demands no less; indeed, the art of lighting a subject may be mastered with tolerable completeness, while posing may never be thoroughly acquired, because it is less of a mechanical accomplishment. It calls for a knowledge of harmony of lines, and the effect of balancing of parts—what, in short, is described as composition, and which every one does not naturally possess. An operator may fail in this, just as painters sometimes do, who, though good colourists, are defective as draughtsmen and in the ability to conceive a good picture. We sometimes feel that photography is too literal to be artistic. From a client's point of view, its tendency is to exaggerate the imperfections rather than the *perfections* of face and figure. Should you have a stout figure to photograph, the neck, as a rule, will appear short. To obviate this appearance in the portrait, it is best to adopt a standing pose, with the camera a little below the level of the head. If a sitting position is chosen, undue height will be given to the shoulders, and the shortness of neck will be emphasised. In treating the opposite extreme—a thin figure with sloping shoulders (not so objectionable in the gentle as in the sterner sex)—I would recommend a sitting pose, and in the case of gentlemen, especially when the head is large, a little drapery, in the form of an overcoat loosely thrown back. The head should be turned in the reverse direction from the angle at which the body is placed, which will help to give the appearance of substance and harmony to the figure, and altogether make the picture more pleasing. A little attention of this sort will improve defects in the sitter just as easily as the want of it may produce them where they ought not to exist. As a rule, twist the figure as little as possible when the person is stout. Some people turn the head more gracefully in one direction than in another; the head seems balanced in the one case, while in the other it may be the line of the neck and shoulder forms too great an angle. Should it be necessary to take that view of the face which gives prominence to this defect, turn the figure away, and the head towards the camera.

WILLIAM CROOKE.

(To be continued.)

CAMERA CLUB CONFERENCE.

DISCUSSION.

THE papers (already published) which were read at the morning sitting were by Messrs. Adeock, Burton, and Traill Taylor. Previous to the reading of his paper *On Studies*, Mr. Adeock remarked that it was not written for those present, but to be read by those who were tyros in photography like himself.

Captain Abney opened the discussion by calling attention to the illustrations of the lecture exhibited on the walls of the Hall by Mr. Adeock—studies of hands, of feet, of figure, and of still life.

Rev. Mr. Lambert felt himself in harmony with Mr. Adeock in his treatment of the subject. His own introduction to photography was through the artistic door. The time required for painting and studying tree anatomy in the open in winter was too long to be endured. In regard to figure work he referred to the exaggeration by the lens of nearer objects, such as the hands. From the study of art collections, he found that at certain periods of art history there was a tendency amongst artists to diminish the size of hands in portraiture. He thought the camera would be a safeguard to keep near to the proper proportions; it was certainly

useful to artists, especially in cloud and wave studies, and still more in tree anatomy.

Mr. Austin wished to know more particularly why Beach's developer was called a "rut." He had succeeded in producing uniformly bad results with every developer, but he had certainly seen the highest quality of work from a use of Beach. It seemed to be regarded as the photographic slough of despond.

Mr. O'Farrell said the hands in most figure work were in a different plane from the principal parts of the subject, and of necessity suffered from exaggeration. In this way photography would rather mislead than assist the artist. It might be interesting and useful to artists to photograph trees bare in winter, and then to make a careful comparative study in connection with photographs of the same trees clothed in summer time.

Captain Abney made reference to Mr. H. P. Robinson as working out every picture on paper in monochrome before arranging the compositions for photographing. For instance, *Bringing Home the May* and *Dawn and Sunset* were examples of this method. From much association with artists he could say that the hands were regarded as expressive of character as much as the face. One of the greatest portrait painters of the day seemed to be in the habit of avoiding the hands. There seemed to be some danger of drawing in the Board schools being suppressed unless influence should be brought to bear to continue it. He then referred to the distortion caused by lenses. If a lens of shorter focus than the natural focus of the eye be employed the perspective is exaggerated, and, in enlarging, the exaggeration is increased. He believed direct large pictures, particularly with near objects, better than enlargements. In a figure subject the sitter was half the artist and the honour greatly due to him. The sitter who claimed part credit for an artistic figure study of himself could by no means have applied to him the ironical story of the organ blower, who said, "How beautifully we played last Sunday." He thought the eye should be constantly educated by a mental study of every scene. As to the use of photography in representing waves and movements of animals he considered these were never seen as rendered by photography. The persistence of vision caused a composite effect, for instance, lines of light on sea in sunlight were seen by the eye and not dots as shown by the instantaneous photograph. The movements of the legs of horses in motion, too, were atrociously inartistic, and, he thought he might add, untruthful.

Mr. Adeock said he regarded Beach's developer as a "rut" from an aptness to be prejudiced against anything new that suddenly displaced long trusted formulae. The ten per cent. solutions of pyro, ammonia, and bromide, he thought, a far less mechanical developer. He could not controvert Captain Abney in regard to his remarks on enlarging. Notwithstanding his recent conversion to enlarging he had to admit that his examples shown were taken direct with a large Dallmeyer's rapid rectilinear lens of more than thirty inches focus. He had been led to his subject by consideration of a picture in one of the illustrated periodicals, the *Century*, of the hand of Abraham Lincoln. He had wondered whether it were really a faithful representation of his hand. The value of a correct record of the characters of great men as shown in their hands would be of great value.

TESTING THE SENSITIVENESS OF PLATES. (By W. K. Burton.)

Mr. Webber said he would like to be informed what effect the depth of film on a plate had in regard to its sensitiveness. Plates of recent make seemed to be decidedly thinner and did not give the range of tones of the early plates. He thought that the makers stinted the amount of emulsion.

Mr. O'Farrell asked whether it was not more a question of the quantity of silver in the plate rather than the thickness of the emulsion.

Captain Abney said he was not one of those who regarded sensitometers as perfect indicators, but they gave a very good idea as to the sensitiveness of plates. Screens as now made were not uniform. He then gave his reasons why he considered Spurge's the best form. In a good plate rapidity was required, and, another point, more particularly gradation. No thin-film plate will give gradation from one to twenty-three, some only as far as eight. Thickness of film was essential to give gradation though the thin plate might be equally sensitive. In regard to phosphorescent screens he had not found those he had kept embedded in paraffine decay. They had retained their luminosity with him for several years. Some were simply painted with Balmann's oil paint, and the oil appeared to cause the tablet to deteriorate. He differed from Mr. Burton as to the effect of the iodide with phosphorescent screen, and illustrated his contention by a diagram to show the dip in the curve of sensitiveness for iodide at the point where the phosphorescent light was emitted.

Mr. Burton would emphasise the remarks made by Captain Abney as to the necessity for thickness of film. In thin films the scale of light recorded was reduced, early reversal was caused, and he fancied sensitiveness also was diminished. Much less light was probably absorbed by thin than by thick films, but he had been unable to observe it. As to the decadence of phosphorescent screens, one he had kept in paraffine was disintegrated, only some spots giving light.

Mr. Sage thought every plate maker ought to put the sensitometer number on their boxes of plates. He then asked leave to refer to the remarks on Beach's developer, and asked what objections could be raised to an ordinary potash developer.

Captain Abney said Beach's developer did not allow such latitude. He thought the pyro potash might be a good developer if used with

brains. He did not believe in the term over exposure; it was the relation of exposure and developer that governed the final result. He had secured good pictures from plates many times over exposed—they were, in fact, properly exposed for the developer he employed.

AMATEUR ENLARGING ON A SMALL SCALE. (By J. Traill Taylor.)

Mr. Webber made inquiry as to the increase of heat in the lantern from using two burners.

In reply to inquiries from Dr. Foulerton, Mr. Taylor remarked that the small plano-convex lens acted somewhat the part of a condenser in addition to the other ordinary condenser.

Mr. Wormald asked for the number of the burner used.

Mr. York said he used an ordinary fish globe as condenser and doubled the light, and suggested the inversion of one of the burners.

Mr. H. Trueman Wood referred to the incandescent gaslight where a cap of muslin dipped in certain metallic salts was placed over the burner. The source of light, however, was rather a large one for lantern purposes. There was a difficulty in lighting up more than a 5×4 plate except by daylight. He had used a large bottle of water successfully as a condenser, but the light was not strong, being lost in passing. No condenser was absolutely required for small work; ground-glass or tissue-paper might be used to diffuse and equalise the light all over the plate.

Mr. Lucas asked how long it was after lighting the lamp before the albo-carbon material was sufficiently melted to come into action.

Captain Abney had tried the incandescent gas or Auer-Welsbach light. There was three times the amount of blue light in it that was found in the ordinary gas flame. The cap of muslin was dipped in salts of zirconium and lanthanum. The light was so intensely white as to be disliked by ladies on account of its being unbecoming for the complexion, a distinct advantage in photography. The heat ray, too, was small compared with what ordinarily obtained. Only one-third the exposure would be required for the same amount of apparent light. Mr. Taylor's plan of using a small second lens as condenser near the flame was one already adopted for military purposes in throwing light over surrounding stretches of country.

In reply to questions from Dr. Foulerton and others,

Mr. Swift said he thought the light was to be obtained, or could be shortly, as he understood the Company interested in it had offices at 4, Jeffrey-square, E.C.

Mr. Taylor, in reply, said that the inverting of one of the burners, as suggested by Mr. York, was not necessary, for, by the suitable placing of the diaphragm, its aperture was opposite a uniformly bright flame. The size of burner used was No. 2. Although his experience with the incandescent gaslight spoken of by Mr. Trueman Wood was only limited owing to its not yet having been introduced commercially, yet had he had considerable experience with that form of incandescent burner in which platinum gauze was employed instead of Dr. Auer's system of muslin. An objection to the former was the great length of the chimney necessary in order to create a draught sufficient to render the platinum incandescent, otherwise it was excellent. In order to melt the albo-carbon material quickly, he lifted the reservoir out of its socket, and by holding it over the gas for a minute it was ready for use at once instead of having to wait till it melted in the ordinary course. Reverting to what he had seen of the two modern incandescent gaslights the Lewis, or platinum, and the Welsbach, he thought that for producing enlargements the former appeared the better of the two, but he could not speak definitely as to this.

Dr. Foulerton said he thought the flame of the gas against wire would cause a very unpleasant smell.

Captain Abney stated that the flame against the wire would set up production of acetylene, a very unpleasant and noxious gas. He then conveyed the hearty thanks of the meeting to Mr. Traill Taylor for his interesting communication.

In the afternoon after members, friends, and visitors had met in the club rooms to see the exhibition of pictures and apparatus there, the Conference was continued at three p.m. by the reading of a paper on

THE SULPHURATION OF PLATINOTYPE PRINTS. (By H. H. O'Farrell.)

Mr. Willis showed that though the paper might be yellowed by sulphuration, a yellowing not difficult to remove, the image in platino-type was not affected. After perfect washing he had never succeeded in yellowing with H₂S.

Mr. Adeock dwelt on the beauty of platino-type and advised those present to "try platino-type and believe in it."

Captain Abney said the permanence of the image was independent of the discolouration by sulphuretted hydrogen. Silver prints could be as permanent as any other, but the organic sulphides formed in the albumen itself were the source of trouble. There were two forms of matter more permanent than any other—carbon and platinum.

The second paper at the afternoon sitting was

ISOCROMATIC PHOTOGRAPHY (by W. H. Hyslop),

and this was taken in immediate conjunction with an address by Captain Abney upon the same subject, in which he sought to demonstrate that orthochromatic plates would not be serviceable to the landscape photographer. He had come to this conclusion from a series of experiments

which he proceeded to explain to the meeting by means of diagram illustrations on the screen. The orthochromatic plates might be useful in taking white clouds on a blue sky, and in photographing sunset scenes, but for ordinary work they would be valueless. The blue must be reduced if orthochromatism is to be made of use. Instead of a yellow screen in copying work he used a hemispherical reflector painted yellow inside.

Some of the pictures taken by the aid of this reflector were thrown on the screen, and compared with others of the same subjects on ordinary plates, and exhibited very striking advantages in favour of those on the treated plates exposed to yellow light from the reflector.

At the conclusion of his paper, Mr. Hyslop made an important communication. He said the question had been asked at a recent meeting of the Photographic Society of Great Britain, whether paper negatives could be successfully treated with orthochromatising substances, as in the case of glass. He was able to answer this question in the affirmative, as he had with him some stripping films which he had successfully subjected to the process. These were handed round.

Mr. Burton regretted to hear the unfavourable conclusions Captain Abney had come to in regard to the use of orthochromatic plates in landscape work. He had been looking to a great improvement in results from their use, and was still unable to understand the marvellous superiority shown in certain landscape pictures from orthochromatic negatives over those of same subject from ordinary plates, except that this result was secured by the orthochromatising.

Mr. Wollaston asked which Mr. Hyslop considered his best result.

Mr. Mackie asked what plates Mr. Hyslop had used, bromide or bromo-iodide, and whether he had tried the effect of orthochromatising the chloride.

After remarks from Mr. Garnett and Rev. Mr. Lambert, Mr. Henderson being called upon by the President, said he had secured orthochromatic effect by use of vegetable dyes. He obtained the effect also without the use of yellow glass. He was not sure that they were not ignoring white light and making yellow light the high lights of the picture. He exhibited some orthochromatic photographs of diagrams containing blue and yellow.

Mr. Wollaston had used Clayton & Tailfer's plates with good results. He considered it was a great deal a matter of exposure.

Mr. Hyslop said that example treated with chloride of silver and erythrosine was the best. He did not think Mr. Henderson's tests were reliable as his diagrams copied contained only blue and yellow.

Captain Abney said he had seen the landscape pictures referred to by Mr. Burton. He could say those plates he had made would only show advantage in taking sunset scenes.

The last paper of the day was one sent by Mr. A. Pringle to be read entitled

RATIONAL DEVELOPMENT.

It was addressed "To my *Camarades* in Camera convened, to be read if convenient."

Captain Abney, in opening the discussion, said this would be the proper opportunity to discuss the Beach developer, as there seemed to be a desire to make an Aunt Sally of it at this meeting.

Mr. Burton approved of ten per cent. solutions, and marvelled at the prevailing habit of mixing the bromide and the ammonia in one solution. If you must mix it should apparently be the pyro and the bromide as these had acted somewhat in the same way.

Mr. Conrad championed ferrous oxalate.

Mr. Wollaston preferred potash to ammonia in developing negatives of dark interiors. With thick films, too, in certain brands he thought it much better, and on paper negatives he found potash greatly superior to ammonia.

Mr. Mackie said there was a tendency to get into a groove and use one developer for every make of plate. He considered this a most important point. Different brands of plates should have different developers. With Beach passable negatives might be produced on almost any plate, but not first-rate negatives.

Mr. Hyslop said, in regard to hydrokinone, that he had found the most wonderful latitude with it, exposures varying from sixteen seconds to more than a minute yielding results almost inappreciably different.

Mr. Burton doubted whether the same gradation of light was obtained with the use of ferrous oxalate.

Captain Abney noted that Mr. Pringle claimed lightness, *allegria*, from slow development; in music it was just the other way. The potash developer might be a good one, but Beach's modification was unscientific in the way it was prepared, in fact he might say it was childish: a chemist's shop which happened to develop. The additions to the pyro and the potash in it were decidedly injurious to the films of the negatives. Hydrokinone was better with potash than with ammonia. He thought there was the same amount of latitude with ferrous oxalate. The great objection to it was that it was expensive.

The Conference proceedings were then closed by a congratulatory address from the President.

In the evening the first annual dinner for members and friends came off at the Holborn Restaurant, Captain Abney presiding. Some excellent songs and speeches were given during the evening, and the company included representatives of the provincial societies, and of the photographic press, the whole numbering about eighty.

Our Editorial Table.

THE PHOTOGRAPHIC TIMES ANNUAL.
New York.

It is creditable to the enterprise of the Scovill Manufacturing Company that they should endeavour to have America adequately represented among the Annuals of the world. That for 1887 recently issued by this well-known firm is under the editorial management of Mr. C. W. Canfield, a former Secretary of the Society of New York Amateurs, who has had the good sense to get up the work on strictly English lines. It is well printed on stout paper and in large bold type, and contains a number of articles which will prove both interesting and useful.

PRACTICAL AMATEUR PHOTOGRAPHY.

By C. C. VEVEES, Leeds.

This little manual has been written as a simple text-book for the beginner. We can cordially recommend it for the purpose intended.

SUPPLEMENT TO CHOICE AND USE OF LENSES.

MR. DALLMEYER, following up his suggestion for the alteration of the Photographic Society's standard, made in our columns on September 24, 1886, has forwarded to us a list of his lenses with their respective diaphragms, all calculated upon the standard then proposed, and now adopted by him. For the guidance of those who possess the lenses with their diaphragms stamped according to the old arrangement, Mr. Dallmeyer has printed in the table the old notation of the stops. The diameter of each diaphragm, its intensity, ratio, relative rapidity, and comparison with the Photographic Society's standard, are all noted. The author, however, draws our attention to the fact that the apertures of the diaphragms of some of the smaller view lenses have been very slightly altered (beginning with lens No. 40,501), but the apertures of the stops of lenses before that number are exactly as given in the present "table of relative rapidities," &c., in the sixth edition of *The Choice and Use of Photographic Lenses*. The value of the table is increased by the fact of its being printed on one large sheet, so that it can be hung in the studio, or any section might conveniently be cut out and placed in a note-book, or even attached to the corresponding lens itself. Mr. Dallmeyer intends this table as a supplement to the pamphlet on lenses referred to, the enlarged edition of which we have already noticed.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At a meeting of the above Association, held on Thursday night, February 10, at the Masons Hall Tavern, City, London, Mr. A. L. Henderson presided.

The CHAIRMAN exhibited some pieces of a bromide print which had been bleached by Mr. F. M. Edwards with chlorine water, and which he (the Chairman) had taken home and put in a dish of water standing near a window; after a long time the chloride of silver blackened again in the daylight and the image had been for the greater part restored. He intended to do more with the pieces, and hoped to effect the complete restoration of the portions of the image.

Mr. URIE, of Glasgow, exhibited some rows of prints taken with his printing machine, to which, he said, a developing machine in its early rough stage had been fitted up as an adjunct, so that the prints were turned out at the rate of one thousand per hour from one negative; some other negatives worked at slower rates. When warm tones were desired seven seconds' exposure per print were given instead of one second. These mechanical inventions were likely to make photographic art of more commercial value and in new grooves.

Mr. B. J. EDWARDS thought that he was the first to point out that tones could be varied by varying the exposures; a long exposure and weak developer gave very red prints. He did not know that it was necessary to tone black prints at all.

The CHAIRMAN here exhibited some of Mr. Urie's rejected prints, which he (the Chairman) had toned after the original fixing and transformed into beautiful prints of great richness; he was doubtful, however, whether this final treatment with gold would not in the long run cause the gelatine of the prints to discolour. He had used about one grain of chloride of gold to twelve or twenty grains of acetate of soda rendered neutral by chalk and afterwards slightly acidified with a very minute trace of acetic acid; eight or ten ounces of water were used in the above toning bath to each grain of gold.

Mr. EDWARDS had brought home from New Zealand some prints most richly toned by a photographer there who used very nearly the foregoing formula, and all the prints toned in that acid bath had since faded, whereas prints toned in an alkaline bath had not done so.

The CHAIRMAN had turned out permanent prints after mixing sulphuric acid with the fixing bath.

Mr. A. HADDON asked if sulphocyanide of potassium, when used in tolerably strong solution, would dissolve gelatine.

Mr. W. M. ASHMAN said that a Belgian photographer had published that such was the case.

Mr. J. B. B. WELLINGTON had been trying more experiments with orthochromatic photography, until his plates had become so sensitive to red that printing went on through the red rim of Warnerke's sensitometer screen. Orthochromatic plates gave no halation, and in that respect were very valuable for interiors.

Mr. EDWARDS had found them to be remarkably good for varieties of foliage.

The CHAIRMAN said that Captain Abney had recently publicly stated that he thought that orthochromatic plates would not prove so advantageous as expected.

Mr. A. MACKIE remarked that Captain Abney based the foregoing statement upon the fact that most of the light reflected from leaves is white.

Mr. W. E. DEBENHAM had found orthochromatic plates to be particularly useful in photographing green colours.

The CHAIRMAN had stained plates with saffron, cochineal, litmus, and anatto, and they had all given orthochromatic effect irrespective of colour, because, as he supposed, they modified the high lights; the things he had named were not in the patent of Mr. Edwards.

Mr. EDWARDS said that the substances named had been used before, and he himself had obtained good results with saffron. The true orthochromatic effects were, however, produced only with a chemical organic compound of silver; the dyes merely helped, as in the use of yellow glass. The chemical method would in ten seconds give that which required one hour and a half by the optical method.

Mr. DEBENHAM stated that two years ago Dr. Eder had published that an emulsion might be made orthochromatic first and washed afterwards.

Mr. WELLINGTON had failed to retain the orthochromatic effect after the washing.

The CHAIRMAN asked what was Mr. Edwards's test for the use of eosine after the orthochromatic emulsion had been washed.

Mr. EDWARDS refused to answer. Some discharged aniline dyes could be restored.

Mr. WELLINGTON thought blue light was the best one in which to develop such orthochromatic plates as he had been preparing; blue gave the best protection for the purpose when testing with the sensitometer.

Mr. DEBENHAM said that blue light was bad to work by, because it had such feeble action upon the nerves of vision.

The CHAIRMAN's very sensitive plates for gaslight exposures were more sensitive to the red than to the yellow rays, and so were all ammonia emulsions; yellow-green screens acted best with them, as tested by experiment.

Mr. EDWARDS had been testing, and did not find orthochromatic plates less sensitive to the reds than were ordinary plates; sometimes they were a little better.

Mr. WELLINGTON's eosine plates gave worse results with the reds than did ordinary plates.

Mr. HADDON thought that the superiority of yellow over ruby light for the particular plates mentioned by the Chairman might perhaps be an error, the real cause of the difference being that with the yellow light a translucent and not transparent screen was employed, and that would greatly lower the general amount of transmitted light of all kinds.

The CHAIRMAN responded that he had always said that spectrum experiments were necessary to settle such questions.

Mr. W. Willis and Mr. C. Irving were elected members of the Association, and the meeting broke up.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

The ordinary meeting of the above was held on Thursday, February 10, at the Free Public Library,—Mr. J. A. Forrest (President) in the chair, with a fair attendance of members.

Messrs. Sylvester Parry (Chester), Alfred Matthews, and Charles B. Reader, were elected members of the Association.

Mr. FORREST wished to draw the attention of members to the weekly reunions held on Wednesdays, at four o'clock, at the Merchants' Café, 25, Lord-street, Liverpool. These meetings have been in existence some time, are quite informal, and have proved themselves a valuable adjunct to the monthly meetings, where, with so many things always on the tapis, a great deal neces-

sarily gets crowded out for want of time. He (Mr. Forrest) would be glad if the members of the Liverpool Association would co-operate with him in these "socials," and by their presence help to make them even more successful than they are; he wished to be permitted to extend the right hand of good fellowship to the Liverpool Association, and, if invitation was considered necessary, he invited them most heartily, as he felt the two Associations should fraternise more than they did, and especially so with regard to the excursions, which he thought might be arranged for the mutual pleasure and convenience of all.

After some discussion, it was resolved that silver and bronze medals shall be awarded at the next competition in lieu of the prizes of prints hitherto offered, as it was felt the medals would act as an incentive, and induce members to take part more largely in the various competitions.

Mr. P. Lange exhibited an excellent 12x10 enlargement from a half-plate negative, printed in platinotype, of two beagles (not the biped species), which were greatly admired.

Mr. H. H. Williams exhibited some whole-plate Woolbury tissue negatives and prints therefrom; in the latter there was no perceptible trace of granularity whatever.

The Secretary also showed a large number of prints taken during a ten days' holiday in the Mourne Mountains, North of Ireland, last Christmas, which helped to illustrate some of the beauties of this photographically forsaken part of "that most distressful country," where a camera still excites as much interest as an express train would to an Esquimaux.

Mr. A. W. BEER then read his paper, *A Holiday in the North Riding; or, On the Trail of the Artists*, which was listened to with attention, and, by the frequent bursts of applause bestowed upon it, his audience were evidently alive to the trouble and pains he had taken to make it interesting with camera and pen.

The first scent of the "trail" is found at Whitby, i.e., the east side, or Old Whitby, the western portion being modern and fashionable. Whitby and jet are terms as synonymous as coals and Newcastle, but fashion and lack of supply have sadly interfered with this part of its once staple trade, and it is only at Haggerlyth we are introduced to a few of the houses once occupied by the miners, now sadly out of the perpendicular owing to a late landslide. Whitby Abbey, built A.D. 657, is as full of pictures as it has quaint legends connected with it. The Fish Market affords some interesting figure studies, as Mr. Du Manoir has found out and illustrated with his versatile pencil. The curious but ugly old Tasean Town Hall reminds us of the primitive place we are visiting by still slightly ringing the curfew. Whitby's once proud whaling fleet, now reduced to dry-drotting in the sun, afford interest to many of the views to be found on the shore. Along the cliffs now to Sandesend, close to which are the great demesnes of the Marquis of Northampton, who affords every facility to artists, who find plenty of work on the remains of the once feudal stronghold, Mulgrave Castle. Scrambling along the cliffs, noticing the old jet mines in their face on the way, on past what is left of Kettlewell, wonderful Runswick is reached, where the houses seem to form part of the cliff itself; it is in every sense a place of negatives, as here there is no church, no chapel, no horse, no cart, no policeman, no post office, no graveyard, no public-house, no photographic society, no social board, and, as a natural consequence, no rates. Still along the cliffs to Staithes, which is larger than Runswick or Sandesend. Here Captain Cook was apprenticed to a grocer, but the house has been claimed by the sea some years ago. A mile up the Esk, and Runswick is reached; then from Eborac to Glaisdale, where every possible variety of river scenery may be had, on to the Beggars' Bridge, which is 200 years old, and is said to be a veritable "Lovers' Bridge" owing to a legend, but one is more prepared to see Tam o' Shanter pursued by Cutty Sark than lovers on it, so closely does it resemble the Brig o' Doon. Six miles south of Whitby, St. Robin Hood's bay and town are reached, and afford many capital "bits," but its quaint beauty is doomed, a grand hotel being about to be built on the cliffs. The train now whisks us away through the Vale of Pickering, and we notice *en route* Pickering's ruined castle, Kirkham's famous caves and old church, to Helmsley, where, amidst the fine trees of Duneombie Park, towers the venerable Keep of Helmsley Castle, which was destroyed by the Parliamentary Vandals of A.D. 1644. In a corner of the castle yard remains the square mullion-windowed building said to have been the residence of Villiers, Duke of Buckingham, where he retired after disgrace at Court. Close to Helmsley is the Monastery of Rievaulx, which is full of pictures, and the ruins of which are most extensive—indeed, in the parlance of a countryman, "There's acres of 'em." From Rievaulx we reach Seavton and Byland Abbey, on to Coxwold village, owned by Sir George Wombwell, of Balclutha fame, and visit in the neighbourhood Shandy Hall, where Lawrence Sterne lived for seven years as vicar, and wrote many of his best-known books. Through some lovely country, we reach the end of our journey, namely, Durham [some lovely slides of which "brought down the house," and "our guide" was thanked by acclamation, without even the more formal vote of the President].

Mr. Beer, who took the late prize at the Liverpool Association for lantern slides, illustrated his paper with over a hundred views, reduced from 10x8 negatives, many of them most artistically coloured, which increased their beauty considerably.

Mr. Cornish manipulated his lantern without a hitch, and had a brilliant light. A very hearty vote of thanks to him broke up the meeting at a late hour.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

At the usual bi-monthly meeting held at Myddelton Hall, Islington, N., on Tuesday, February 15, Mr. J. Traill Taylor, President, in the chair.

The HON. SECRETARY read a communication from Mr. F. B. Taylor referring to the negative shown by Mr. F. W. Cox at the last meeting.

The following gentlemen, who were members of the original North London Society, were nominated by the Council as honorary members:—Messrs. W. Ackland, W. Bedford, E. Dunmore, E. W. Foxlee, D. W. Hill, J. Martin, and G. Shadbolt; and the following as ordinary members:—Messrs. H. Dinmock and H. Inray.

Several presentations were made for the Society's library.

Mr. TAYLOR, vacating the chair, which was taken by Mr. A. Mackie, Vice-President, then delivered a lecture on the characteristics of the photographic lenses in everyday use. Commencing with the portrait lens, he explained the great influence of the back combination not alone in conferring intensity of the image by shortening the focus, but especially in flattening the field, showing by what means a round field could, by a slight modification, be rendered flat. Such defects as astigmatism, and not working to focus, were treated of, and remedial measures indicated, together with the best position for placing the diaphragm in order to secure certain ends. The employment of this lens for

lantern projection was dwelt upon at some length, and the conditions for obtaining the best marginal definition on a flat field pointed out. Modern single achromatic landscape lenses next claimed attention, and it was shown that for certain classes of large heads these would prove very useful. The conditions under which such lenses would give a soft definition coupled with rapidity of action were shown, and an explanation given of the means whereby the front lens of a portrait combination could be used alone for portraits of large dimensions as well as for landscapes. The class of doublet lenses known as rapid claimed a large portion of the speaker's attention during his discourse. He explained by what means the flattest possible field could be obtained while using a large aperture, and dwelt at some length on the flare spot in the centre of the field, to which so many of these lenses were liable when employed out of doors with a small stop, explaining cause of this fault and showing the means by which it could be cured without affecting the working of the lens otherwise, and further explaining by what means the rapid doublet could be converted into a wide-angle lens. But, he said, while a good rapid doublet might be made to embrace a wide angle by having a supplementary short mount, an originally wide-angle lens could not be converted into one working with great rapidity. The subject of comparing and testing lenses, the employment of the single parts of compound lenses for landscapes at long ranges, the care of lenses, conjugate foci, and other topics of a practical nature, including that of the best form of mounting lenses, all received their meed of attention during the discourse, which lasted over an hour, and during which several lenses of various forms were exhibited.

The VICE-PRESIDENT said he felt sure he was expressing the feelings of every one present as well as his own in saying that he had been gratified as well as instructed by the President's able and interesting discourse. He hoped to have an animated discussion, and felt sure Mr. Taylor would answer any questions and explain anything that he might not have made clear.

Mr. P. SPENCER said that he should like Mr. Taylor to explain the reason of the existence of both chemical and visual foci in some lenses.

The reason of this Mr. Taylor then demonstrated on the blackboard.

Mr. F. W. Cox believed that many years ago Mr. Taylor showed at the Photographic Society of Scotland a lens he had made to give diffusion of focus at will, and asked whether there was any lens made that would give such diffusion of focus. He thought such an one would give very artistic effects.

Mr. E. DUNMORE had taken pictures with a Dallmeyer's portrait lens in which this quality could be obtained by separating the back combination.

Mr. J. T. CHINN asked whether there was any rule for fixing the distance of the stop from the lens in single lenses.

Mr. TAYLOR said that no rule could be laid down. The best position of the stop could best be fixed by a system of trial and error.

Dr. LANDSAY-JOHNSON asked why some makers made the lenses of their wide-angle rectilinear very small while others made them so much larger.

Mr. TAYLOR explained and demonstrated that in the former case the same results are obtained by using very thick lenses, which in the latter was obtained by using thin ones of larger diameter.

Mr. F. W. HART spoke on the subject of flare spots in single lenses.

After some remarks by Mr. George Smith and others, and owing to the lateness of the hour, the discussion was adjourned until the next meeting on Tuesday, March 1, which will also be a lantern evening.

The proceedings terminated with a hearty vote of thanks to Mr. Taylor.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

The usual fortnightly meeting was held at the Technical Schools, Bridge-street, Birmingham, on Thursday, the 10th instant,—Mr. E. H. Jaques in the chair.

The minutes of the last meeting were read and confirmed.

Mr. Frank Edwards was elected a member, and Messrs. Leeson and Hoskins were nominated for election.

The evening was devoted to a lantern exhibition of slides for a prize given by an anonymous member for the best slide shown on the screen, Messrs. Birkett, Button, Collins, Fowler, Dr. Harts, Harrison, Holliday, Jaques, Karlse, Middleton, Pickard, Pumphrey, Riley, Robinson, T. Taylor, R. P. Taylor, and Tylar, competing, the result being that fifteen slides were selected as the best, which are reserved for the final decision of the judging committee.

Some very fine slides, not for competition, were also shown by Messrs. Barwell, Heaton, Pumphrey, and Welford, which were much admired. About two hundred slides were shown.

The meeting was most enjoyable, and it was decided to promote similar exhibitions during the year.

The subject of next meeting will be *Developers and Rapidity*.

YORKSHIRE COLLEGE PHOTOGRAPHIC CLUB.

The ordinary monthly meeting was held in the College on Friday, February 11,—The President (Mr. C. H. Bothamley) in the chair.

The President showed some specimens of orthochromatic photography.

The Rev. R. W. ATKINSON, M.A., gave a lecture entitled *Here and There in Norway*, which was illustrated by a large number of very fine lantern slides.

A vote of thanks to Mr. Atkinson, on the motion of Mr. W. THOMAS, seconded by Dr. E. H. JACOB, concluded the proceedings.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on the 9th instant,—Mr. George Bankart, President, in the chair.

Mr. B. Smith was elected a member.

Mr. T. S. TAYLOR, assisted by Mr. W. TAYLOR, then proceeded to give a paper on *Lenses*, which was illustrated with several experiments and demonstrations, assisted with diagrams thrown on the screen by the oxyhydrogen light. Mr. Taylor first showed the effect of interposing a prism and prisms in

the path of a ray of light, demonstrating the deflection caused thereby, and with numerous diagrams he showed the various angles and foci determined by lenses of different shapes and densities; explaining the reason, by practical examples, for using a combination of lenses composed of glass of different composition, as flint, crown, &c.; and, after showing practically the formation of portrait, rectilinear, and other combinations, he closed by showing the various stages of manufacture from the rough glass to the finished lens, which, being a new experience to the members, was thoroughly appreciated and enjoyed.

CHELTEMHAM PHOTOGRAPHIC SOCIETY.

MONTHLY meeting held February 10.—Mr. Baynham Jones in the chair.

The SECRETARY exhibited some prints on Liesegang's "Aristo" paper, stating that he found a difficulty in toning it satisfactorily. He had first tried the ordinary borax bath, which produced no effect; the next batch were toned with a bath containing ammonium sulphocyanide and sodic phosphate, and the results were better, but not quite satisfactory.

Mr. Jones showed Vergara's slide for the Woodbury tissue and a transparency printed on a Woodbury film. This was quite free from any appearance of granularity.

The Eastman Company had sent for exhibition some specimens of enlargements on their bromide paper, and also some negatives taken on their new stripping paper. These latter were very much admired, being as clear as glass, and showing a marvellous amount of detail.

A vote of thanks was passed to the Eastman Company and to the Woodbury Tissue Company for their exhibits.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

AN ordinary meeting of the above Association was held on Thursday, February 3, in the South Glasgow Exhibition.

The PRESIDENT, Mr. W. Laing, jun., occupied the chair, and explained to the members that it had been thought advisable to hold the meeting in the Photographic Exhibition, as it would close on the 5th instant, and by doing so they would have an opportunity of again examining this most interesting collection. This was the reason of the change of place of meeting. They were indebted to Mr. Paton for putting a room at their service, and he thought the Association could not do less than accord to Mr. Paton a very hearty vote of thanks for the many facilities he had allowed the members during the time the Exhibition had remained open.

The minutes were thereafter read and confirmed.

A letter was read from the local Secretary of the Photographic Convention Committee, but it was agreed to hold consideration of the same over till next meeting.

A number of Eastman prints by M. Nadar, Paris, and sent to the meeting by Messrs. G. Mason & Co., Glasgow, were passed round and greatly admired, a conversation taking place on the merits of the Eastman and kindred argentic papers.

Mr. URIE said that this process of printing was sure to come to the front. It had three distinct qualifications over albumenised paper, namely, it was cheaper; it was quicker in printing, over two thousand a day being printed easily; and it was permanent. In the pictures before them he thought, however, the deep shadows might have had more of an engraving black about them, and this could have been got by having the shadows in the negative clear glass.

Mr. PATON did not know that it would have improved the pictures to have them blacker in the shadows. He had always found that they had a much softer and pleasanter effect when the shadows were not too dark.

Mr. URIE said he did not mean that the picture should be hard, but what he wished to show was that the blacks in these pictures were dull and flat, and what an artist would do were he working up one of them would be to brush over the shadows with gum or varnish, so as to make them more brilliant. This, however, that an artist would do could all be done by having a proper negative and developing carefully.

Mr. G. BELL said it was wonderful how good an enlargement could be produced on this paper from a very inferior negative. He had occasion to take a group rather late in the afternoon, when most of the light had gone; instead of wasting a large plate, as he knew it would be useless to attempt a large size, he used a quarter-plate; the resulting negative proved almost useless, giving an exceedingly poor print on albumenised paper; yet this same negative, when placed in the lantern, yielded on argentic paper an extremely good 18x14 enlargement.

After some further conversation, a vote of thanks was given Messrs. G. Mason & Co. for allowing the members an opportunity of examining these beautiful pictures.

The CHAIRMAN then asked the Secretary to read his paper, entitled *Some Photographic Illustrations from the Works of O. W. Holmes*.

At the close the Secretary was awarded a vote of thanks, and the members then proceeded to go over the Exhibition and examine the different exhibits, and thereafter the meeting separated.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE fourth meeting of the current session was held on February 2.—The President occupying the chair.

Five gentlemen were elected ordinary members, and four nominations were made for election in March.

Mr. WILLIAM CROOKE read a paper on *Photographic Portraiture* [see page 104], which elicited considerable discussion amongst the professional members.

Mr. J. McKEAN said the usual preference was for a north light in the studio, when it could be got, but he was compelled often to make use of a south light, and found it quite suitable except in brilliant sunshine.

Mr. F. MOFFAT thought the suggestion to use tissue-paper as an aid to the proper lighting of deep-set eyes a good idea.

Mr. J. HOWIE thought the idea of several preliminary sittings being given before a large work was undertaken ought to find favour and recommend itself. Photography was distinguished for a realism and truth which were not at all times picturesque, still these qualities were so valuable that they alone were sufficient to make our art ever hold its own.

Mr. H. BIBBS said he used at times as a reflector a screen covered with reddish blotting-paper. It conveyed a soft flesh-coloured light to the face.

Mr. W. T. BASHFORD said the hints given were very useful, but like other good rules, had their exceptions. Each sitter requires to be considered on his own merits, and peculiar cases will run counter to all ordinary rules.

Mr. FORGAN referred to Mr. Crooke's remarks upon the eye as conveying mainly the expression of the mind, so that, though the lower part of the face were hid, the eyes alone would tell what passion ruled at the moment. He thought that, expressive as the eyes were, it commonly needed all the features to unmistakably interpret mental emotions.

Mr. WILLIAM HUME showed how a quite efficient enlarging apparatus could be improvised out of an ordinary packing box, by making a few simple adaptations. He also exhibited a number of gelatino-bromide enlargements made by it. The means by which the sensitised sheet was placed in the exact position desired, after focussing, was ingenious. Three drawing studs were placed in a triangular form as guides, and the paper placed quite up to them and fixed there. Mr. Hume used a condenser, but no reflector.

Mr. FORGAN recommended that a large portrait combination should always be preferred to a rapid rectilinear, in enlarging, because of the more general illumination it gave.

Mr. TURNBULL said that when lamp flames were employed they should be set edgewise to the lens; large spread flames did not do so well.

Mr. ANNAN and Mr. CRAIG-CHRISTIE each exhibited one photograph containing phantom images, but which was positively declared by their respective authors to be the production of a single exposure.

A good deal of discussion ensued, and many explanations were offered, but nothing which was satisfactory—at least to the producers.

The meeting was brought to a conclusion by a distribution of over seventy photographs by ballot to the members.

PHOTOGRAPHIC SOCIETY OF IRELAND.

THE usual monthly meeting of the above Society was held on Friday last, the 11th instant, in the Royal College of Science, Dublin.—Mr. S. Baker in the chair.

After the reading of the minutes Mr. Greenwood Pim exhibited a novel changing bag, which was nothing more nor less than a light black indiarubber coat. This he buttoned down the front and laid on the table buttons down, then doubled the sleeves and tucked them under, then with two little elastic bands, one round the neck and the other round the tail, both hands could be inserted light-tight as well as the box of plates and dark slide, and the plates changed by feel alone.

Mr. Meldon also showed a bag which he was in the habit of using, and which had a small window of red stuff in one side and a couple of eye-holes fitted in a face-piece, which was held close to the face by an elastic band, so that plates could be changed by sight.

Mr. J. L. ROBINSON then read his paper, entitled *A Week in Kent*, after which a number of photographs which he took on the excursion were passed through the lantern.

The report of the judges of the pictures sent in for the competition in work done last season was received, and the two medals were awarded, the one to George Mansfield, for his picture, *Old Street in Saltes Basses, Pyrenees*, and the other to Dr. Brown, for *A River Scene*. There were a very large number of pictures sent in for the competition.

A vote of thanks to the judges, Dr. Hayes and Mr. Longfield, was proposed by Mr. PIM, and passed unanimously.

Correspondence.

Ed. Correspondents should never write on both sides of the paper.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

To the EDITORS.

GENTLEMEN,—May the Committee again trespass upon your courtesy for space to notify photographers that the Annual General Meeting of members has been fixed for Monday evening next, February 21, at 181A, Aldersgate-street, E.C.2? The chair will be taken at eight p.m. by J. Traill Taylor.

It is further desirable to mention that much useful work, within the legitimate scope of such an Association, has hitherto been but partially carried out, owing to the limited number of subscribers, whose position rendered it unlikely for them to tax the Society's resources. Suffering and misfortune has not been absent in circles photographic, but in the majority of cases that have fallen under the notice of the Committee the essential qualification of membership was absent. The feeling has grown that an annual payment of 10s. was beyond the capabilities of many whose earnings are often slender and variable, and that the Society would be of greater general benefit were subscriptions lowered in order to embrace all conditions of workers—namely, 2s. 6d. per annum. This innovation, which the Committee regard as a bold experiment, has now been brought about, with the result of adding at least fifty members within a very short period.

Non-members are invited to be present and take part in the discussion, but members only are entitled to vote.—I am, yours, &c.,
February 14, 1887. H. HARLAND, *Secretary*.

ORTHOCHROMATIC PLATES IN LANDSCAPE PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—In your editorial note of last week referring to Captain Abney's remark that the real use of isochromatic plates will be in the copying of paintings, you go on to say, "Are not paintings transcripts of nature, not only as regards drawing, but also colour?"

I think you rather misunderstand what Captain Abney *did* say. Will you allow me, as one also present at the meeting, to explain what I understood to be Captain Abney's meaning? He showed that all coloured objects, and even black objects, reflected a certain proportion of white light. It is this white light that in landscape photography impresses the image on the plate. The coloured rays, *within the narrow limits of time in which a landscape picture is taken*, have no sensible effect on the plate. In copying pictures the conditions are different. A protracted exposure is given, and yellow light or a yellow screen is used.

The coming season will doubtless solve the question. Meanwhile, I would like to draw attention to two facts: (1), that a plate treated by Messrs. Dixon's method is two or three times *faster* than the same plate untreated; (2), that in copying pictures *by daylight* the orthochromatic plate, even *without* a yellow screen, gives an indisputably better result. These facts would seem to cast some doubt on Captain Abney's view.—I am, yours, &c.,
H. H. O'FARRELL.

To the Editors.

GENTLEMEN,—Will you kindly allow us space to correct one or two inaccuracies in Mr. W. H. Hyslop's paper which appears in your last number?

Mr. Hyslop assumes that "had Messrs. Dixon not issued their plates the Tailfer patent would not have been so much heard of," and that we should not have purchased our English interest in it. As a matter of fact, negotiations for the English licence were commenced as soon as we were convinced that the patent was a valid one in this country, now more than a year ago, and the purchase was practically completed long before the plates prepared by Messrs. Dixon were put upon the market. It is to be regretted that Mr. Hyslop did not take the trouble to ascertain the facts before making his statement.

With regard to Mr. Hyslop's assertion "that our isochromatic plates will give no such effect without a screen," we have only to point out that all the examples shown by us at the meeting of the Photographic Society of Great Britain were taken in ordinary daylight without a coloured screen of any kind. This conclusive fact was stated at the time, and can easily be demonstrated by any one who chooses to make a simple experiment.

Mr. Hyslop's paper contains many other statements which, to say the least, are misleading, more especially in the description of his failures, which in every instance he attributes to his chemicals, instead of fairly ascribing some share of his non-success to his own confessed want of chemical knowledge of the subject.—We are, yours, &c.,
The Grove, Hackney, February 14, 1887. B. J. EDWARDS & Co.

AMATEUR PROFESSIONALS.

To the Editors.

GENTLEMEN,—Mr. Adeock in his remarks on my letter seems to put a pointed reference to a clerk amateur becoming a professional that I did not quite mean. I have been a clerk, and wish no offence to that useful class; it was just a handy name. I might as well have said baker, brewer, night watchman, barber, signalman, joiner, teacher, or anything else, and I happen to know all these; and what I call them is amateur professionals, because they make profit out of the practice of the art-science. And I do not object to any one becoming full fledged professionals. It would not become me to do so. I had my time of honoured amateurism and of successful professionalism, and should I get into the sere and yellow leaf of an old duffer, I must just take it, but will try to keep that off as far as possible. That does not keep me from thinking that it would be well for those who acknowledge themselves professionals to have a society of their own for trade purposes in the widest sense. Our societies and our journals used to be for the advancement of the photographic art, and all who took an interest in it became members; now fine lines and blurred lines are being drawn to separate the amateur from the professional. Whether my sight is failing in such matters I don't know, but I cannot find much difference yet, and think all might sit on the same benches and read the same journals. But purely business affairs might well be discussed by professionals themselves by themselves. The amateurs are particular to discuss all things affecting them. Then their journal with its pictures, its prizes, &c., carries on the work, all well in its way, and with an editor who is evidently an amateur in many things. He can distinguish what an

amateur and professional might do on Sunday, and can say what is wrong in newspaper and Government interference with an officer using his camera at an execution, and can tell about what the magistrate should do about lent pictures and nude pictures, in fact, he seems lawyer, theologian, legislator, artist, and critic all in one. So, Gentlemen, I say professionals ought to have a trades union of their own; and I again commend your leader to the consideration of those who live by photography.—I am, yours, &c.,
Glasgow, February, 1887. ARCHIBALD ROBERTSON.

"SULPHURATION OF BROMIDE AND PLATINUM PRINTS."— A REPLY.

To the Editors.

GENTLEMEN,—I will now deal with Mr. Andrew Pringle's remarks on platinotype, which appear in an article in your issue of January 7, but before doing so will suggest that it is a pity that he did not deliberate longer and more anxiously, as he puts it, before writing the article.

First let me deal with the title of the article, and then I will go on to answer the salient points in the body of the paper, indicating them by stating paragraph and line.

Why does Mr. Pringle *himself* term prints made by the platinotype process "platinum" prints? He says they are but slightly composed of platinum, and it cannot be that he should say that he is using the accepted title, because the accepted title is "platinotype."

Third paragraph, fourth line.—I have used the term "absolute permanency" because some have affirmed that a print may rightly be called "permanent" which will last twenty, thirty, or perhaps fifty years, and no longer. Now, I own that such a process would be a vast gain upon albumenised paper, especially if any of the periods could be *insured* in the case of each print carefully treated in the making. But while such a process would be valuable, if otherwise good, there are other processes which can give an image—a deposit in half tones—"absolutely" as "permanent" as the paper itself; and to these I give the term "absolutely permanent"—it has been often used and accepted—to differentiate from the "permanency" of some writers of the present day.

Carbon and platinum are known to be not only unassailable by sulphuric acid, but to pretty well every chemical and treatment besides. It is, further, of some value that these bodies are more lasting than paper, because we have all the more assurance that they will not from some accident fail us in the most important records which it is intended to preserve.

Then, as to the "white" support, which in another sense forms a part of the "image," we want proof or evidence that it, too, will not alter sufficiently to spoil the picture during the existence of the paper (at least that the paper support shall be as good as any other paper of same age). Now, did all platinotypes behave as Mr. Pringle's prints have done, it might look bad for the future appearance of the lightest parts of the prints. But it has been proved over and over again that a properly produced platinotype (*the conditions are known*) is not affected by sulphuric acid, or by many other chemicals.

Despite Mr. Pringle's assertion, I will say that a "permanent image" on a not "decayed" but degraded sheet of paper, *is better than* a "fading image" upon a "permanent" sheet of paper, and this not only in an artistic sense (it is even *certain* that some prefer the prints which have impure "whites"), but in a scientific one also. Who would care much in A.D. 2000 whether certain prints representing, say, London scenes and life as it was in A.D. 1887, were not quite immaculate, or far from it, in the "whites?" But if every face showed only what looked like little holes in a mask, what boobies they would think us for not having used the more permanent methods of printing! The inscribed tiles of the ancient Egyptians are not, if we come to word-splitting, "permanent;" but as I have stated elsewhere, many terms we use do not bear very rigid dissection, but we all know the significance of them.

Fifth paragraph, ninth line.—My "trilogy of letters" (how grand! Mr. Pringle has nearly enough matter in his *one* article for a so grand a thing as a "trilogy of letters!") contained some very sound arguments, though Mr. Pringle may think it may prove "riling" to state the contrary. A metal in fine division is known to chemists to be more readily attacked by chemicals which can combine with it than is the metal in the "lump." Silver and zinc are granulated for dissolving; platinum dissolves with fearful energy in warm *aqua regia* when in fine division, but quite slowly when in "lump." And it is always found that the chemical which will affect a metal in the "lump" will also affect it in the powder, and generally *vice versa*. Hence I say, if silver in the lump is attacked by substances, so also is silver in fine division; and from what we know, the effect may more rapidly take place in the latter than in the former case, though I do not press that part of the subject.

I contend that there is "analogy" between silver in the "lump" and precipitated silver, though a hundred Mr. Pringles stated the contrary. "Analogy" is defined in my dictionary (edited by a Scotchman) to be "an agreement or correspondence in certain respects between things otherwise different." There is some bond stronger, perhaps, than "analogy" between the two forms of silver; if so, all the better for my argument. I know that persons have put forward a supposed tarnishing of platinum coins as analogical evidence against platinotype.

And they would have had a pretty strong case against it, but for the unfortunate fact that platinum coins do not *tarnish*, but are often very dirty from lying about. They are not now coined in Russia. So much for argument and "analogy." But stay a moment. What has Mr. Pringle to say to the "analogy" of the surface of my negatives (not printed from) suffering alteration in impure air in a year or two? If the image of a negative alters, why not that of a positive? Perhaps there is no "analogy"—perhaps so—it is *sameness*. I do not give any reasons (like Mr. Pringle) or one reason only, but speak out according to my knowledge, and support my statements by facts which are most suggestive—they are not put forward as proof.

If autotypes were "not uninfluenced" by the treatment accorded them, why does Mr. Pringle dismiss them with so much honour and good report? Have not autotypes, as well as platinotypes, been asserted "long enough" to be "permanent," so that "persons have come to believe and to assume the thing stated?" Mr. Pringle, "saucer for the goose is sauce for the gander." I do not write this wishing to egg Mr. Pringle on to saying anything against the prints of the Autotype Company, but merely to show how biased and one-sided he is. It would be more dangerous, too, to venture against the older autotype process than to attack platinotype—that patented anathema.

Seventh paragraph, third line.—Mr. Pringle really deserves a regular flagellation. He knows as well as I do that the platinotype process is not known as "permanent" just because the Platinotype Company have asserted it to be so. Yet this is what he would have his readers believe. Such men as Captain Abney, Mr. John Spiller, and M. Vidal (see JOURNAL for December 31), believe it to be a thoroughly permanent process—as far as any yet known. Besides, he imputes to the Platinotype Company in their "successful assertion" something like dishonesty; for can he suppose that the Company do not know as much of the behaviour of the prints in sulph. hyd. as he does?

Ninth paragraph, sixth line.—Mr. Pringle states very charitably that I was "assuming everything . . . to suit" my "own argument," and "without the least apparent consideration as to whether" my "foundation is firm or not." Now I don't know that any milder term or expression is applicable to this statement than the one that it is a "thumping lie." I suppose Mr. Pringle tries to make out that I stated that certain chemicals absolutely *do* affect in the ways instanced in respect to "lump" silver, the bromide prints. I wrote nothing of the kind (this kind of disclaimer, as Mr. Pringle would say, for the "twentieth time"), but simply to the effect that our knowledge of these effects on silver in various forms gave pause to the *absolute assertion* of "permanency" of the bromide prints.

Eleventh paragraph.—And now we come to the wonderful experiment, the result of which has made platinum "pop in" and silver "pop out!" By the way, I do hope that his sulph. hyd. was *pure*, and that no trace of sulphuric acid or of iron contaminated it; I suppose there could have been no "copper!"

First of all, Mr. Pringle "catches" his platinotypes, and then proceeds to "cook" them. However, instead of making them himself with his "usual care," he procures two prints from different workers, and presumes that they are creditable examples of the platinotype method, treated in such a manner (according to directions, supplemented, where directions are not applicable, bulk of baths, &c., by common sense) that the sensitising and other salts have been removed during "clearing" from the paper.

Twelfth paragraph.—Two sentences, if they mean anything to speak of, would seem to be another attempt to place me and my statements in an untrue and unfavourable light. Mr. Pringle says "it will take a good deal to make me" (himself) "think otherwise" (alluding to the greater stability of bromide over albumenised prints), and "Mr. Berkeley may wish to continue the test, but I do not." Now Mr. Pringle's belief has been my opinion all through my writings, and is foreshadowed in the sentence Mr. Pringle himself quotes, "Let the statement go forth," &c.

Thirteenth paragraph.—Mr. Pringle made bromide prints with his "usual care." (He says with "probably less than usual care," but then explains that they were "*under exposed*.") He treats them with sulph. hyd., and finds, he says, no visible effect. But will Mr. Pringle aver that the "*image*" has not been converted, or partially so, into silver sulphide? He treats the platinum prints in a similar manner, but he will not, I presume, tell us that the "*image*" (commonly called "platinum") underwent any change whatever. Presuming this to be so, the evidence is, from this point of view, more favourable to platinotype than to the bromide prints.

But presuming a silver sulphide image is formed, I am not by any means sure—when this means for forming it has been taken—that the image has lost any of its stability by the change. It is not that sulphide of silver is particularly unstable (the sulphurising method of intensification with "liver of sulphur" (pot. sulphide) has been rather favourably known in that connection for many years past); the danger, I take it, in—what I may call—"natural sulphurisation" is that the image may be affected differently so far as to produce different and uneven tints.

However, I am not now, any more than previously, going to say that such and such effects will take place. I merely point out, in the absence of proof or of evidence of permanency, that the fact of an image being liable to attack from very various chemicals (this, by the way, not being the case with the platinotype "image") forms ground for grave doubts

as to that stability some of us know by the term "permanency." This is nothing more nor less than the line of argument that was—or would have been—taken by disinterested persons in the case of platinotype, had it not stood the tests applied to it by a skilled chemist and others. It is precisely on account of the result of such experiments that the platinotype process was able "from the outset" to be termed "permanent," with only the occasional demurrer of men of peculiar views, like Mr. Pringle. But men can be found to demur to everything, even to stating that the world is not "round" but flat. However, the question at issue is not the characteristics of platinotype but of bromide prints, and Mr. Pringle will not "whitewash" the one by "blackening" the other. The only reason why I have imported platinotype into the question, is that I wished to show that in all fairness the approved method of testing prints for claim of "permanency" at the "outset" of a process should apply to bromide prints equally as to platinotype prints. The origin of the argument is *not mine*, but is due to "disinterested amateurs" and others.

Fifteenth paragraph, third line.—Why does Mr. Pringle assume that had he used the sulphurous acid stronger the platinotype would, he "dare say, have gone wrong?" And this after so much preaching on the subject of alleged assumptions. His object must have been to show his impartiality; but he does not succeed—not quite! Mr. Pringle then (fifth line) passes over a test or two not favourable to bromide prints, and proceeds to say that "sulphuration was Mr. Berkeley's cry;" so it was, but it was *not* my only cry, neither do I confine myself to one mode of sulphuration.

Nineteenth line.—If the face of the prints is more discoloured than the backs, one of two things would appear to be indicated: either that the prints were cleared for *too short a time* (overworked baths is the usual cause of improper clearing), or that the paper when cleared was old or partially decomposed (ferrie chloride). However, I make this statement under a certain reserve, not knowing the facts, nor having seen the prints.

Sixteenth paragraph, fifth line.—"Damp, I am always told." Indeed! O just judge and truthful witness! Do you not call to mind that you have been told that no doubt your *negatives* have had much to do with the dull, flat character of your prints? Do you not remember that there was a suggestion that you should send two or three negatives to the Platinotype Company so that they might be tested? And are you not aware that you have not availed yourself of the offer? I allude to this little episode because it shows the spite of the words, "Damp, I am always told." Seeing that others succeed with the paper supplied to them, the inference is that the "usual care" of Mr. Pringle is not sufficient for working so simple a process as the printing and development of platinotype paper. This is the inference derivable from the words; but I think better of Mr. Pringle's ability to do all necessary (except apparently the negatives) than I do of his boasted impartiality.

Seventeenth paragraph, second line.—It is satisfactory to know that Mr. Pringle "maintains" that platinotype prints are "permanent," even though he classes them after bromide prints. But then, what is "permanency?" It appears to be like "truth—hid in a well." After writing what he does in the twelfth paragraph, he proceeds to tell us that "even albumen silver prints may, perhaps, be called 'permanent,' so far as sulphuration is concerned." How funny it all is!

Eighteenth paragraph.—Is not the positive assertion of permanency made by the manufacturers of the bromide paper "supposititious speculation?" I neither have made a positive statement nor condemned any products whatsoever. There is here room for the parable of the "mote" and "beam"—but, no; not in your pages, Messrs. Editors!

Nineteenth paragraph.—I will just hint to Mr. Pringle that chlorine is found in the air; also sulphuric acid; also ozone.

And now, having stated that any future tests will not affect what he has written, he proceeds, in the postscript, to inform us that the first bromide prints tested (the "under exposed" ones) were less pure in the "whites" than a print subsequently tested; and that "this time the bromide print has suffered more deterioration than the platinum ones" (how fond he now is of calling platinotype "*platinum*!"). It appears, then, that in the case of the "first prints" the discolouration produced may have been *masked* by an original dinginess of the "whites." If so, much of Mr. Pringle's assertion falls, for the present, to the ground—even from his own point of view.—I am, yours, &c.,

HERBERT B. BERKELEY.

San Remo, January 15.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column: but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, good view lens in exchange for a revolving stereoscope.—Address, W. SAUNDERS, Dickleburgh, Seole.

Will exchange three oil paintings for whole-plate or 10×8 bellows camera.—Address, R. WHITEHEAD, The Studio, Grays, Essex.

Several numbers of JOURNALS and News offered for chair backs (faucy).—Address, WILLIAM THORNTON, Lockwood-road, Huddersfield.

- Will exchange 100 photographic lantern slides for quarter-plate camera complete.—Address, R. J. SHEERMAN, 147, Clarence-road, Lower Clapton.
- Dissolving view lantern for limelight, complete, in exchange for whole-plate portable camera and rapid rectilinear lens.—Address, EASON & Co., 16, Dalston-lane, N.
- I will exchange concert cocoa-wood flute, with six silver keys, also a camera lucida, for a half-plate bellows camera.—Address, A. B., 3, Chapel-terrace, Malahide, Co. Dublin.
- Offer, Meaglier's best whole-plate landscape camera with three double backs, in solid leather case. Want, Dallmeyer's 2B and 3A lenses.—Address, A., 179, Lord-street, Southport.
- Wanted, an old-fashioned view lens (menisens) of long focus; will give a good changing box for whole-plates and under.—Address, BUNGOYNE, 345, Coventry-road, Birmingham.
- Will exchange eight volumes of THE BRITISH JOURNAL OF PHOTOGRAPHY (four bound in cloth) for 10×8 or 8½×6½ rectilinear or symmetrical lens.—Address, JOSEPH FOWLER, 126, Castle-street, Glasgow.
- A first-rate quarter-plate double combination lens in exchange for a whole-plate camera, square, bellows body, to expand about twenty inches, for copying, &c.—Address, MANAGER, Midland Studio, Harborne, Staffordshire.
- Lantern with three-inch condensers, achromatic front lens, with fifteen coloured Scripture slides in wood frames and six comic slipping slides in frames. Wanted, good whole-plate or cabinet burnisher.—Address, T. L., 26, Earl-street, Coventry.
- For exchange, last seven years' JOURNAL, 12×10 copying camera, half-plate portrait lens, half-plate repeating-back camera, and tripod stand. Wanted, whole-plate portrait lens and camera, and 12×10 view lens.—Address, W. B., 32, Stoke-road, Guildford.
- Will exchange, boat, oar, and water-piece complete, for interior background; also 5×4 pocket camera, by Shew, with two double and one single dark slides, for quarter-plate camera with or without slides.—Address, GEORGE C. RADFORD, The Studio, Mansfield.
- Will exchange THE BRITISH JOURNAL OF PHOTOGRAPHY and *Photographic News*, without picture supplements and unbound, for the years 1884, 1885, 1886, for a good whole-plate view or instantograph lens.—Address, M. H., 31, Sarah-street, Newcastle-on-Tyne.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

- H. HATTON, 36, Leeds-road, Dewsbury.—Two photographs of R. E. Lockwood in jersey and cap.
- William Usherwood, 32, High-street, Dorking.—"Derby-place," 1886.
- Anderson & Son, Dalry, Ayrshire.—Portrait of J. Ewing in walking suit.
- Thomas H. Radford, Tower-road, Aston.—Photograph of Aston-villa Football Club.
- Thomas Thorburn, Prestwich, Ayr.—Three Portraits of the Champion Mount St. Bernard Dog, "Save."
- A. P.—Send specimen of your work.
- WILLIAM GREY.—The *Bulletin Belge* may be ordered through Triibner, Ludgate-hill, London.
- J. J. BROWN.—We are unable to say to what impurity the opaque spots on the negative are due.
- OX.—The canvas enclosed is well adapted for breaking up the emulsion. No fault arises on that score.
- LUX (Burnley).—The largest of the portrait lenses named will be the most useful for daylight enlarging.
- CHAS. BOWDEN.—A fairly good six-inch double condenser may be obtained for £3. Either gas or oil lamp will serve for enlarging.
- H. E. DAVIS.—When your shutter is complete we will be glad to see it. Any letter sent here for the author of the article will be forwarded.
- TUESDAY.—To remove the stains from the fingers, try a saturated solution of alum to which a liberal allowance of sulphuric acid has been added.
- WM. MCC.—By all means decide upon the lens of the rapid type. The portrait lens, though quicker, will not be nearly so suitable for your purpose.
- R. S.—The print appears to be a collotype of German production. These prints are produced in Germany by machine printing at a very cheap rate.
- Q. H. D. C.—It will cost you but little to send the lens here, when we will be able to examine it and correct the defect; failing which we can show it to the maker.
- GWENT.—For over exposure add to the developer a solution of bromide of potassium. See Article for Inexperienced Photographers in the issue of the 4th instant, page 74.
- L. DIXON.—To develop micro-photographs so as to bear a power of an inch it is necessary that pyrogallie acid be employed. Iron will produce a too-granular deposit.
- G. AINSLEY.—We see no reason why, under the circumstances, you should not use the picture as a specimen. Certainly the sitter cannot prevent you doing so if you choose.
- R. A. JOHNS.—The spots are due to the plates themselves, and not to anything in the manipulation. There is no remedy but to either make fresh or purchase some of the commercial plates.
- S. B.—Innumerable methods for imparting a colour to prints have been employed. We can offer no opinion as to the merits of yours until we know something concerning it, or, at any rate, see a specimen.

J. CHESTER JARVIS.—Willesden paper will afford the protection required for the damp wall. The firm from whom you may purchase it will afford every information as to the best means of causing it to adhere.

VACUUS CANTANS VIATOR.—The propensity of a lens to give a flare spot can be removed. See report of meeting of North London Society on another page. The address in question will eventually be published *in extenso*.

ELLEN HILL.—The reason of the failures is that the prints are very much over-toned. Fifteen grains of chloride of gold in forty-five ounces of water is far too much. One grain of gold to eight or ten ounces of water is a far better proportion, as then the action is much more regular and better under control, particularly in the hands of a novice.

TYRO asks: "Can you tell me what fixative is used for charcoal or carbon drawings? How is it made and how applied? I have been doing some drawings and find the charcoal rubs off."—If the drawings be floated upon or immersed in skim milk the pigment will become fixed. Detailed information on the subject will be found in any of the manuals on crayon drawing.

AMATEUR asks: "Would you kindly answer in your 'Answers to Correspondents' what is the best preparation for mounting the rim photographs on the glass? and what is the best preparation for the black used as a mask?"—There is nothing better than a dilute solution of gelatine applied in the way we have so often described. For the black portion of the mounts Bates's black varnish or Brunswick black will answer; the former dries the quicker.

OBSERVER writes: "As I intend to erect a studio with a north-east light, and am at a loss for the proper proportions, I will feel obliged by replies in your paper to the following questions:—1. Is thirty-six by fourteen feet sufficient floor space for all purposes of family groups and general photography?—2. Is eight feet sufficient height from floor to eaves?—3. The proper pitch for roof, so as to reduce the trouble from the sun to a minimum."—1. The proportions proposed will answer quite well, though for groups, particularly if many figures have to be included, a greater width would be desirable. If the groups are only composed of three or four figures, fourteen feet will be sufficient.—2. The height will be sufficient.—3. The pitch of the roof should not be less than forty-five degrees. Galvanised iron or zinc.—The address is Willesden Paper Works, Willesden, N.W.

NOVICE sends some of his attempts at carbon printing, and asks the reason of the small spots with which the prints are studded. He says the spots are more prevalent after the tissue has been kept a few days than when it is used the day after sensitising.—The spots may arise from several causes. They may be due to insoluble particles in the tissue itself, though this is scarcely likely to be the case. We suspect that particles of some substance gets in contact with the tissue whilst in a moist condition, and so sets up an insolubility. Particles of pyrogallie acid, if floating about in the room in which the tissue was dried, would fully account for the evil; so would particles of alum, sulphate of iron, and many other substances used in the dark room. Dry particles of bichromate of potash will also cause specks of insolubility if they come in contact with the moist tissue. The remedy is obvious supposing the trouble arises from the suggested source.

REV. HENRY B. HARE.—1. "Collotype" is a term created for the purpose of signifying a print obtained by a process analogous to lithography. A stout plate of glass is coated with gelatine and bichromate of potash; when dry it is printed under a negative; afterwards sponged with water, which is absorbed by the parts protected from the light, whereas those portions on which the light acts fully are hardened and resist the penetration of the water. Ink is then applied by the lithographic ink roller, and impressions obtained in the usual way. The picture of the Derby Convention in our volume for last year was printed in this manner. We shall bear in mind your suggestion concerning a detailed account of the process.—2. With regard to what you designate the "stupid and unprovoked attack" in the pages of the famous contemporary named, and concerning which the Council of the Camera Club speak in even stronger terms of denunciation and repudiation than those employed by you, it was looked upon by the person attacked with amusement, knowing as he does that "*Quem Jupiter vult perdere* &c."

PHOTOGRAPHIC CLUB.—At the next meeting of this Club the discussion will be on lantern matters. This is a lantern night. Visitors are invited.

PHOTOGRAPHING A BULLET.—Dr. Riegler, of Pesth, is said to have just made a very curious experiment in photography, and one that to many people will appear almost incredible. He has photographed a bullet after it had been fired from a rifle, and while it was proceeding with a velocity of 440 metres—rather more than a quarter of a mile—a second. A Wernsd infantry rifle was the weapon selected for the purpose of conducting the experiment, which was in every way successful, a perfect reproduction of the bullet being the result. A horse at full gallop, a swallow in its flight, and even a flash of lightning, have succumbed to the photographer's art; but this last triumph is still more marvellous.

No. 1399. VOL. XXXIV.—FEBRUARY 25, 1887.

HOW TO AVOID NEGATIVE BREAKAGE.

THERE have lately been brought under our notice several cases of negatives broken from one particular cause, which, as it is of such a nature as might possibly escape observation if attention were not drawn to it, we have thought a description might be of sufficient interest to bring before our readers, as our words may serve as a warning to provide against mishaps, through similar existing but unobserved causes, with other photographers. At the same time we may take note of additional untoward circumstances of a kindred nature. Doubtless the one we refer to is no novelty to some of our readers who have the handling of large numbers of negatives, and the suggestions we have to make are probably such as have been acted upon by them.

The line of breakage in the untoward experiences we describe have all commenced at the corner of the negatives, and after one or two instances had been shown to us we suggested that the stock of unexposed dry plates should be examined to ascertain whether they were not, when received, already injured. Our suggestion led to the discovery of several plates at one or other corner of which rudimentary danger in the form of an exceedingly minute crack could be discerned upon close examination, such examination as would rarely be given under ordinary circumstances. Now it is morally certain that a negative with a minute crack at one corner is bound to give way eventually. It may survive, under favourable circumstances, the printing of many copies, or it may "go" the first time it is put into printing. We would therefore suggest that, as, in the handling of plates before packing, and of the packages themselves when being stored, occasional injury to a corner is not an exceedingly improbable occurrence, every negative taken should be most closely scrutinised before being printed from, as at that stage of the crack all evil may be prevented by the simple method of cutting off with a diamond the whole corner of the glass containing the crack. This, however, must be done most cautiously, or the crack will spread instantly, perhaps from corner to corner. After examining the injured corner by turning it in all directions, so as to discover the furthest point to which the injury extends—and we may note that it is remarkable to how great a distance it may extend without being noticed—the negative, entirely freed from any foreign matter which may adhere to it, should be placed upon a perfectly flat surface—a piece of plate glass is the best—and a diamond cut made with a firm hand across the corner. If the cut does not go across the crack itself the negative will then be perfectly safe; but in printing it will be advisable, as a precautionary measure, to use a frame with a plate glass front, so as to distribute the pressure.

But instances will occur when the split extends so far that to remove a piece of glass containing it would be detrimental to the picture required. In this case we still say it would be tempting fate to print from it, and the plan, then, is to lead the crack in the least hurtful direction. Suppose, for example, in a 12×10 negative the crack extended for an inch or so, and rather more towards one side of the plate than the other. A piece of iron slightly pointed (we have seen a thin poker used) should be made red hot and applied to the back of the negative, about a quarter of an inch in front of the crack, which will, in a moment or two, be seen to advance towards the heated iron. Then the iron should be removed—raised from the glass, and not drawn along—and again placed in advance of the crack, which, once more, will follow the iron. This process—one well known to the practical chemist—may be repeated until the crack is led close to the edge of the glass, and then the piece may be separated by a slight pull. At this stage the negative, though rather unsightly, is rendered free from future danger, and should be printed with glass protection as above. If the piece removed contains some portion of the subject that cannot well be spared, it should be cemented with Canada balsam to the other part and always protected by a piece of glass; the crack will then not print, but the operation calls for skilful handling.

Another fruitful source of breakage lies in the thinness of the glass which some makers use for the larger sized plates, with the object, we presume, of avoiding excessive weight. We have seen the danger of this in two different directions. When removing a large plate from the developing tray during the progress of development, a certain amount of "pull" is usually needed either through so-called suction, or adhesion from the gelatine at the back, that so largely distinguishes some brands of plates; but in some makes of trays the sides are irregular enough to slightly imprison the plate, and the "pull," instead of being from the accustomed cause, may arise from the plate being so caught. Hence, with a thin plate a crack is almost inevitable, and is so easily brought about that the actual cause escapes attention, and it is assumed that the crack was there at first, and had spread during the handling. We may say we have been a victim ourselves to this form of accident, though it is quite possible that one of the unnoticed fine cracks above alluded to may have existed, so as to give a start to the breakage.

We have also seen thin negatives broken while being removed from grooved zinc washing troughs, through placing a little transverse pressure upon the glasses, instead of carefully removing them in a perfectly upright direction.

One of the commonest causes of breakages is inequality of pressure in the printing frame, and this may arise in many

ways, the commonest being unevenness of the bed upon which the negative lies. This unevenness may arise through the frame not being true, or through small particles—a minute particle of glass or a splinter of wood from the frame itself—resting on the *rabête*. Such particle of foreign matter may often be present without injury, but if an unusual pressure or a sudden jar be given, the glass is not sufficiently elastic to withstand it, and then, when the print is removed, the negative is found to be broken. An examination will generally reveal the presence of some minute elevation at one end of the line of severance, and it is remarkable how very slight an elevation suffices to produce a rupture of continuity in the substance of the glass. We have seen a circular piece of glass cut out of one plate in a packet, from the uneven pressure of a fine curled-up blade of hay grass accidentally included between two of the plates.

When negatives are wrapped together the emulsion so often found at the backs of plates is a dangerous provocative of breakage. The elasticity of glass is very slight at the best; when it is diminished by cold, or other causes, it may be unable to respond to the slightest irregularity of stress, and it gives way at the point of greatest tension, especially when the irregularity is suddenly produced as by jarring or slight concussion.

In general terms, therefore, we would say that to reduce breakages of negatives to a minimum, let the corners of negatives be uniformly closely scrutinised before placing them in the printing frame, and in handling and storing let the utmost care be observed to avoid the slightest irregularity of pressure.

ORTHOCHROMATIC PHOTOGRAPHY.

It will be remembered that during the past few years we have on many occasions directed attention to the excellence of the reproductions of works of art by Continental photographers, and have urged English artists to give attention to orthochromatic photography, to which the superiority of the foreign work was said to be due. However, since the last Exhibition of the Photographic Society, when Messrs. Dixon & Son showed the results they had achieved in this direction, there has been no lack of interest in the matter. As our readers are aware, it has formed an important topic for discussion at nearly all the metropolitan societies.

At one of the recent meetings of the London and Provincial Photographic Association, Mr. J. B. B. Wellington read a very valuable paper on the subject, and at the Conference of the Camera Club a fortnight ago two important papers were also contributed, the first by Mr. W. H. Hyslop and the second by Captain Abney (not published), both of whom have given considerable attention to the matter. The former gentleman's paper was of a thoroughly practical character, while that by the latter was more particularly devoted to the theoretical part of the question.

Mr. Hyslop, like Messrs. Wellington, Bedford, and many others who have tried it, find that eosine, whatever may be its properties when used with collodion, quite fails to produce the desired effect when used with gelatine. The same may be said with reference to chlorophyl and several other substances which have from time to time been mentioned in connection with collodion. Mr. Hyslop's best effects were obtained by the employment of erythrosine in conjunction with ammonio-chloride of silver, or with citrate of silver, and between the

two there appears to be but little to choose. Mr. Wellington secured his best results with erythrosine and carbonate of silver. The difference between eosine and erythrosine, it may once more be explained, is that the one is a tetrabromfluorescein and the other a tetraiodfluorescein. Some of the results shown at the Conference were quite equal to, and in some respects it was claimed for them that they were better than, those on the commercial plates, the superiority being in the rendering of the reds.

In every case where the best orthochromatic effect was obtained, whatever the chemical agents employed, it was in conjunction with the yellow screen on the lens. Captain Abney, in his experiments, instead of the yellow glass, used a yellow reflector, which he exhibited at the meeting. This is a concave reflector, similar to those used when the electric light is utilised for portraiture, except that it is coloured yellow instead of white on the inside, so that the object to be copied can be illuminated by a yellow light. By this means the same end is attained as by using a yellow glass on the lens. One very important point, alluded to by Mr. Hyslop, in connection with orthochromatic photography should not be overlooked by experimentalists, namely, the value of the reds.

In many of the examples shown at the Conference, the reds, particularly on the commercial plates, were not nearly so well rendered as they were on the ordinary plates. In some instances they came out almost if not quite black, and this appears to be a very general experience with commercial orthochromatic plates. The reds in a painting are of quite as much importance as the yellows or the blues. If they be ignored or come out black in the photograph, it is manifest that whatever advantage is gained in the blues and yellows is at the expense of the reds, as these, it appears, at present are more correctly rendered by ordinary than by orthochromatic plates. Here is a field for further experiment.

In investigating this part of the subject, experimentalists should deal with all colours, and not confine themselves, as some appear to have done of late, simply to blues and yellows. A colour chart, similar to that shown at the Conference by Mr. Hyslop, which we have since had in our possession, appears to be well suited for experimental purposes, and is a most crucial test for any plates, and excellent for comparison. It is constructed as follows:—Strips of coloured paper—two or three shades of each, as well as white and black—about three inches or so wide, are pasted on a large sheet of cardboard; then some narrow strips of the same paper are mounted at right angles across them. By this means a chart is obtained in which each colour or shade is brought into juxtaposition with every other colour or shade. Hence the orthochromatic effect on the negative can be judged of with the greatest nicety, and this cannot be correctly done unless the different test colours are actually brought into contact.

In connection with the subject of orthochromatic photography is an important point for the consideration of photographers namely, how the different colours really should be translated into monochrome. For example, how should the blues, greens, reds, yellows, &c., of a painting be rendered in a photograph so as to convey a correct impression of the original? To make a medium red or blue nearly or quite black, or an orange almost white, is clearly incorrect. It is generally considered that the various colours should be translated according to their luminosity. But this is not always done by engravers, as a comparison of some engravings with the original paintings will prove. Evidently engravers and artists themselves are not all in accord.

on this point, as will often be seen where two plates from the same original have been engraved by different men.

Although photographic plates may now be prepared so that they render colours widely different from what the ordinary ones do, still it is important to bear in mind that they should do it with some approximation to correctness if possible, and not one colour at the expense of another.

Since writing the foregoing, and *apropos* of the subject of orthochromatic photography generally, we have just received the specification of Dr. Vogel's new orthochromatic patent, which will be found on another page. Time at present only permits of our thus briefly referring to it.

DRYING AND MOUNTING GELATINO-CHLORIDE PRINTS.

WHILE writing further upon this subject, it may be remarked here that a great deal of the comfort of stripping depends upon the proper hardening of the surface of the print in the alum bath. If this is not properly done there is frequently great trouble, especially when glass is used, from portions of the surface sticking firmly to the glass. With a properly hardened film, however, there is rarely any trouble of this sort, but if it be desired to make assurance doubly sure, the print may be allowed to dry after hardening, and be again wetted previous to its attachment to glass or other support.

After squeegeeing on to the support, the print must be allowed to dry spontaneously. On no account must heat be resorted to, or portions of the picture will come away from the support whilst the remainder will be permanently fixed. Nor is it advisable to hasten the drying by other means, such as placing the print in a current of air, as this creates a tendency on the part of the portions first dry to leave the support, and so give the print an uneven and "crinkled" character. When perfectly dry, if all has gone on well, the print will leave its support with the greatest ease if a corner be raised with the point of a penknife, and will be perfectly flat and possess a surface glaze dependent upon the material upon which it has been dried.

The surface thus produced will be lowered to a considerable extent in the operation of mounting, though not to the same degree as in the case of a silver or carbon print stripped from collodionised glass. The surface remaining after mounting a gelatino-chloride print much resembles that of an unrolled albumen print, and may be treated in the same manner as the latter if proper precautions be adopted to ensure that the surface is *perfectly dry*, as well as properly lubricated before either rolling or burnishing. The one great point is perfect dryness, and this condition does away with the possibility of employing any liquid lubricant such as alcoholic solution of soap; for the small proportion of water contained in the liquid, as well as some of the alcohol itself, cling so tenaciously to the gelatine surface, that it is next to impossible to drive them off, and the consequence is, on passing the print through the burnisher, that the film sticks, and is abraded or otherwise injured. Powdered talc rubbed well over the dried surface acts as a good lubricant, or, better still, a mixture of talc and finely powdered and perfectly dry Castile soap applied in the same manner. A little of the powder is dusted on to the print and rubbed *gently* until well distributed, after which greater pressure is applied until the soap imparts a slight gloss to the surface. It should then be passed through the

burnisher with as little delay as possible, otherwise the thin film of soap will absorb moisture from the atmosphere, and render the attempt abortive.

In those cases where it is desired to retain the full "enamel" gloss, it will be necessary to proceed in the same manner as in mounting enamelled silver prints, or double transfer carbon prints from glass, namely, the mount must be attached to the print before the latter leaves its temporary support, and mount and print be dried and stripped at the same time. This, of course, is a more troublesome operation, and one that requires some skill in its performance.

A more simple plan, which we have worked experimentally, seems well suited to amateur work, though even in this it must not be expected that success will result unless the utmost care be observed throughout. The method is as follows:—Procure some of the thinnest sheet ebonite obtainable. The Silvertown India-rubber Company, of Cannon-street, supply a suitable article, which is what we have used; it is about the thickness of a stout visiting card, perfectly flexible, and thin enough to transmit a moderately strong light. Cut this into pieces the exact size of the prints to be mounted, that is to say, the size they are to be when attached to the card. Prepare these sheets in the ordinary manner with powdered talc, and squeegee on to them the *untrimmed* prints in the ordinary manner. When half dry, or when they have been some time in contact with the support, let the prints be carefully trimmed with the scissors to the size of the support, taking care that the edges are cut clean. If allowed to become dry, the projecting margins of the print will by their curling detach the print from its support; but as there is no necessity for drying before mounting, the edges may be removed as soon as the print has become well attached to its support.

Having trimmed the print as it lies on its support and before it has become dry, apply to its back any good mountant. The best for the purpose is a warm solution of gelatine with a considerable quantity of alcohol added. Apply this evenly to the print, and then place it, support and all, in position on the card mount, rub down in the ordinary manner, place under pressure or pass through a rolling press. Or Mr. Alexander Cowan's method of mounting is well adapted to this process, in which arrowroot or other mountant is applied to the mount and allowed to dry, when the damp print being placed in position, the whole is passed through a rolling press, the moisture of the print sufficing to ensure instant attachment.

Whichever method is adopted, print and mount must be allowed to become perfectly dry. This may occupy some time, since the moisture must be absorbed into and escape by the mount. For this reason Cowan's method is preferable in consequence of the small quantity of moisture it involves. When perfectly dry, the ebonite support is easily removed by carefully raising one corner, and steadily but firmly peeling it away from the picture. In order to facilitate matters, and to prevent the mountant getting in between the print and its support, it is well to give the latter an edging of vaseline or paraffine to the depth of an eighth of an inch in addition to and after its preparation with talc.

If the high gloss be objectionable, there is no necessity for any of the trouble of drying upon glass or other support. The print after hardening and washing is squeegeed upon glass, as previously described, merely to expel superfluous water and hasten its drying. It is, however, immediately stripped from the glass and hung up to dry in the ordinary way. The curling in drying will be much less than in the

case of albumen paper, and it will when dry be found easier to manipulate than the latter. From this point the treatment of the gelatine paper is identical with that of albumen, only observing the precautions already mentioned with regard to lubricating and burnishing.

From the report of the Annual Meeting of the Photographers' Benevolent Association, which will be found in another page, it will be seen that the door of this Association has been thrown wider open. One of the laws which confined its operations to professional photographers has been altered to embrace all who are *connected* with photography. This is a judicious alteration. It is also noteworthy that the Rev. Mr. Tooth, a philanthropist who holds the keys of a Home for Boys in London, where they are educated and lodged, has most kindly offered to receive one such boy recommended by the Association. We are glad to find that the "Benevolents" have received a large accession to their list of members, and that they are financially in a flourishing condition, although, with a still further increase of funds, their powers for good will be largely augmented.

Most photographers are familiar with the admirable series of portraits by M. Nadar, of Paris, which have been lately shown at the meetings of most of the leading photographic societies of England. They are prints from ordinary negatives on gelatino-bromide paper with a coarse surface, such as that of drawing-paper, and of a fine black tone. The special feature about them to which we wish to direct attention, is the style and treatment in the finishing, which no doubt will become popular. The prints are produced with a pure white margin by masking the negative, so that mounting on cardboard is rendered unnecessary. The prints themselves being merely plate marked are then ready for framing in the same style as an engraving. When so finished they somewhat closely resemble good mezzotint prints. Photographs of a rich black tone—whether they be gelatino-bromide, carbon, or platinotype—finished off in this way have a much more refined appearance, and are far more in accordance with the present improved artistic taste of the public, than when they are mounted in the orthodox cut-out mount with its tawdry gilt bevel.

MASKING negatives at the edges, so that they can be printed with a clean margin, is a very easy matter. One method is to paint neatly round the edge of the negative with black varnish, and then on the reverse side to gum strips of black or non-actinic paper somewhat wider than the margin required. Another plan is to cement broad strips of paper direct upon the face of the negative. The latter is the simpler method, but it has the disadvantage that, unless the paper be very thin, a sharp and well-defined outline, which enhances the beauty of the picture, is not always obtained. Also the occasional expansion and contraction of the paper itself, or its becoming accidentally detached from the glass, is liable to give rise to inconvenience.

THE plate marking of prints, whether mounted or unmounted, which adds so much to their artistic effect, is by no means a difficult operation to any one possessing a rolling press. The best plan, undoubtedly, is to roll the print on a plain polished steel plate with bevelled edges, such as those prepared for engravers. The rolling and plate marking is then accomplished at a single operation. This, however, is seldom done in practice, as a set of steel plates for all the different sizes required would be somewhat costly, besides requiring considerable care to maintain their pristine polish. The plan usually followed is to roll the prints first on the usual bed of the press, and then roll them again with a lighter pressure in contact with a sheet of zinc about the thickness of a stout card, the edges of which have been slightly bevelled. In order to give the plate mark, two or three thicknesses of blanketing, or soft felt, must be interposed between the roller and the print. In place of the zinc, cardboard is often utilised. When this is done it is obvious that the pressure applied must be light, otherwise the surface obtained by the first rolling will be destroyed and that of the cardboard substituted.

It does sound somewhat strange, now that photographers are supplied with their plates ready for exposure and development, to hear that first-class operators are difficult to obtain. Such, however, we are assured by several leading photographers is the fact, and that good operators are as scarce as formerly. In the old collodion days, when a certain, though very limited, chemical knowledge was essential in order to prepare and maintain the different materials in the best working condition, such a difficulty could readily be understood, but now the thing seems incomprehensible.

THE detective department of the police has been the subject of much comment of late with reference to the non-arrest of Currell, of London, although he was never half a dozen miles away from the place where the murder of which he is accused was committed. The defence of the police is that the portrait issued for their guidance was so bad that it was perfectly unrecognisable. There is, no doubt, good ground for this assertion, as every one must admit who saw the wretched prints which were exhibited in every direction. Bad as the block must have been in the first instance, the impressions were rendered much worse than they need have been in the printing, and by the exceedingly common paper employed. It is rumoured that the trouble this matter has caused will bring about an entire rearrangement of the police portraiture. Phototypic blocks of excellent quality can now be obtained at a short notice, and at a moderate price, but they must be somewhat carefully printed and also on a moderately good paper.

SEEING that it occupies some time to prepare a surface block for effecting due publication by the police or others for persons wanted, it is well to realise the fact that faithful silver prints may now be taken from a single negative at the rate of a thousand per day, the quality being all that the most fastidious can desire. We refer, of course, to that system of printing on Alpha paper by Urie's Automatic Printing Machine, and by which our ALMANAC is this year so admirably illustrated. But the doctrine of evolution appears to be active even as regards this machine, for when we received a visit from Mr. Urie, a few days ago, he informed us that, in consequence of still further improvements he had made, he was able to announce that the large number just mentioned might now be increased to twelve thousand prints per day. But in the case of the larger output the tones will be somewhat darker than in that of the lesser number, for in order to obtain warm, light tones, a longer exposure is necessary.

INQUIRY is frequently made as to the best proportions of gelatine, water, and alcohol, to form a medium for mounting photographs without their cockling. It is advisable to use as much spirit as possible, but the proportion that can be introduced, without causing a permanent precipitate, depends upon the strength of the solution and the character of the gelatine itself. The weaker the solution, whatever be its character, the greater the proportion of alcohol that may be employed. If the gelatine be of a strong and tough kind, such as that used for emulsions, far less spirit can be added than is the case with one of a friable quality, like those employed for thickening soups, or of the common glue type, that is, supposing the solutions be of equal strength. For mounting purposes the latter variety of gelatine is far preferable to the former, as more alcohol can be used; added to this the solution does not curdle or gelatinise so quickly, consequently it is more convenient to use. When a solution of gelatine begins to gelatinise before the two surfaces to be attached are brought together, much of its adhesive properties are sacrificed. It is for this reason when making the strongest glue joints, that the solution is always made thin and is applied as hot as possible. With attenuated solutions alcohol may be added to almost any extent without causing precipitation.

METHODS OF RETOUCHING.

II.

A METHOD which finds considerable favour with many English retouchers of experience, consists of filling in or spotting all the leading imperfections and general defects almost completely; that is to say, the pencil is worked carefully over all the transparent spots

specks, lines and other markings, until no trace of them is visible. This done, the inequalities of light and shade, also the modelling of the various features and muscles of the face, are harmonised by a system of straight, or very nearly straight, lines, running in a downward direction. In this treatment the lines must necessarily run across the muscles and lines of the face. Although, as I said, many really good retouchers adopt this method, and some undoubtedly good results are gained by it, I do not at all think it an advisable one to adopt as a model on which to form a special style or method for oneself.

As the reader will observe, there are some points, though few, in this method which may be considered slightly analogous to the method described in the preceding chapter. It will be easy, on examination, to see how very slight, however, is this resemblance when I say it is only to be found in the treatment of the nose and the frontal depression.

In this method, although the lines all take a downward direction, they are very seldom *parallel*, or, to be more correct, perhaps I should say, *equidistant*. Now, this must necessarily detract from the firmness of touch as well as the general quality of the work when finished. Some retouchers, who are more than ordinarily skilful in this method of working, however, make lines so very fine, that they will, under some circumstances, impart the appearance of having been *dotted*. Indeed, when extremely successful, and on a negative which lends itself to this method of working, a result will be produced which might easily pass as having been accomplished by a system of *stippling*. This occurs but seldom, as few negatives will offer favourable opportunities for success. Besides, the effect will be by no means so good as that produced by the bolder and more artistic treatment of the *lines*, and need not, therefore, demand our further attention.

It will be found advantageous to reflect well on all the various methods of working—good, bad, and indifferent—while endeavouring to form one for one's own special use; but care must be taken not to model it upon any system but the best. The knowledge of an inferior method need not make a student fall into the errors of its ways, but rather serve as a warning to keep away from them. It may seem strange that I should lay down the theory that a really good and well defined method should not be adopted by the student and, in fact, become the general treatment for all retouchers. This, however, will be easily understood when I say that *sentiment* (if I may be allowed the expression) is such a necessity to the producing of successful work. It is this very *feeling* or *sentiment* in the retoucher's art that makes it absolutely necessary for each artist to adopt his own particular method, that *system* which will produce in *his* mind the most harmonious and graceful results. There is, relatively, as much sentiment and appreciation in a retoucher's treatment of a head, on a negative, as there is in an artist's colouring of a picture. All artists will not sketch in and colour a portrait according to hard-and-fast lines, but be guided by their *feelings* as to the treatment of their subject. It is this same *feeling* that must guide the retoucher, although in a lesser degree, and in a much humbler work of art.

It is the possession of these artistic feelings that will show to advantage, as a retoucher perfects his style of work, and according to the degree they are possessed so will the excellence of his works be valued. It is *feeling* alone that will preserve *intellect* in a head, while *taste* may prove sufficient to produce a passable work. It is needless to say which would take the palm in the scale of excellence.

In America all the various methods and styles seem to have their fair share of supporters. As a rule, however, the leading retouchers work rather more in a scumbling style, being bound by no rules as to the making of a stroke. Wherever taste suggests or an imperfection requires it there he places his touch. This is very naturally a very convenient manner of working, and when thoroughly experienced can be carried to a very high degree of perfection. But, mark you, one must be truly proficient to succeed in it. Of course in this treatment no particular attention is paid to the direction of the lines of the skin or muscles; at the same time the work will be found to take a more systematic form than what we may describe as scumbling. The nearest I can get to a description of the touch is by calling it a saw-tooth one. If examined with a powerful magnifying glass the shape or character of the markings will be found to closely resemble the "business side" of a saw. The touches are generally made very fine, and produce a very charming effect of stipple when printed. The student can easily see what I mean by carefully examining a few of the American portraits sent over to this country. Sarony and Mora, of New York, have sent us very many beautiful examples of retouching, and are well worthy of the attention of the intending retoucher.

On the Continent of Europe there are many most excellent systems

of retouching. Indeed, generally speaking, they are nearer the perfection of this art than they are either in this country or in America. Although widely different methods may be used in the same town, or even the same studio, by various operators, all seem to get the desired artistic effect to a uniform degree of perfection. I can only account for this by the fact that almost every retoucher on the Continent has had a more or less sound art education. To this they add their natural artistic *feelings* which instinctively guide them all to that point of excellence that the less cultured or commercial retoucher can never hope to arrive. On the Continent excellence is the object one places before them, reasonable time being allowed for the production of first-class work; here I regret to say such is not the case. Here it is a question as regards the result, "Does it pay?" There the sole trouble is, "Is it good and artistic?" This will easily account for the difference between the work produced here and abroad. There are men here daily producing *ordinary* work that, if placed on the same footing as their Continental *confères*, would be found capable of producing results second to none. Here we are commercial or nothing. In many cases it is a question more of "How many heads has he done to-day?" than "What splendid work this man is producing!" By this I do not wish to infer that we cannot hold our own, or that all we do is wrong and everything done on the Continent is perfection. On the contrary, for we will find on examination that large numbers of Continental negatives are manifestly much overworked and the likeness almost, if not absolutely altogether, taken away. But even these, as a rule, please the ignorant public (I hope they will forgive me), and so the majority of the photographers continue their production. I most sincerely wish the public would be less easily gulled by injudicious flattery, as much better works would be the result in thousands of cases where really bad ones now pass muster.

It seems a rather disputed point as to whom the honour of introducing the art of retouching into this country should be awarded. I believe Herr Mohr, of Frankfort-on-the-Maine, however, may fairly be allowed to take the credit. He certainly took the monetary blessings attached to it, if that should prove anything. It is undoubted that a few worked it secretly before his advent, and a very good thing they made of it. Those who thus practised it guarded their secret as a miser would his gold. They kept it from the rest of the profession, who, in their blissful ignorance, wondered at the excellent results produced by their more fortunate, I won't say more enlightened, rivals.

If I mistake not, Mr. Williams, of Regent-street, in those days caused not a little sensation by the marvellous results he then produced. For the first time ladies with badly freckled faces got a presentable portrait. The result was all flocked to his studio to be taken. How time changes all things! The best works turned out by Mr. Williams in those days would stand but a poor chance to-day beside the works of any of our leading firms.

In those days the now old-fashioned plates were in general use, and, of course, were not retouched under the same conditions as the negatives of to-day. Then we had to retouch on the collodion film, either before or after varnishing. In the case under notice colour played as active a part as the pencil. The latter being the better agent has naturally completely distanced its rival. I believe Mr. Williams used colour first, and ultimately used the pencil as well in retouching his negatives. However, he began with using a neutral colour and sometimes a blue to make up the necessary density to do away with the defects in his negatives and so produce those results which brought him in vogue. As I am on this subject I may as well say a few words upon the system of retouching upon the old collodion plates which came into general use shortly after Herr Mohr began to teach it publicly.

The film of the old wet plate, unlike that of its tough, dry successor, was delicate, and would not bear the touch of a pencil. I will not dwell upon its treatment with colour. To impart to the film a necessary power of resistance, and also a tooth to take the plumbago of the pencil, a medium had to be employed. The most common method was to dip each plate in a weak solution of gum, which, when dry, would not only impart a firmness to the film but also a tooth which would greatly facilitate our work. Great care had to be taken not to breathe on the film, as so doing would soften it, and the pencil touching it would cut through. Assuming that the plate is all right for working, we had to treat the negative as laid down for the dry plates, but could not work, of course, with the same boldness or firmness of touch. The pencils used were generally soft, and the touch light. Indeed, the tooth on these old-fashioned negatives gave touch as freely as would drawing-paper. Sometimes, if the least moisture happened to have been absorbed by the film, the negative would come to grief in the varnishing. Indeed, this fact gave rise to the

habit in this country of generally working *after* varnishing, instead of before. In Paris I never saw a negative retouched *after* varnishing, but here I have had to retouch more than nine out of ten on the varnished film. We used to get a fine surface for working upon on the varnish by the application of a medium made up of eighty grains of gum, dissolved in one ounce of benzole. When thoroughly dissolved and filtered, this solution had to be applied to the part needing treatment with a piece of cotton-wool. It dried quickly, and by rubbing it gently with the ball of the finger a perfect surface for working on was procured. If the work did not prove satisfactory, it could be removed by the application of a little benzole, and the work begun over again. Another medium, to be used similarly, was spirits of turpentine, three ounces, and cuttle-fish, one ounce. Another—turpentine, one ounce; gum dammar, ten grains; and Canada balsam, five grains. Another was made by dissolving ten grains of clear resin in one ounce of benzole: allow to settle for a day or two before using. I worked without any medium for years, however, on Hubbard's varnish, with the greatest ease and success. It is not necessary, however, to worry much over these matters, as they belong to the long past. Still they all have an interest to an intending retoucher.

REDMOND BARRETT.

PHOTOGRAPHIC PORTRAITURE.*

ALLOW me to say a few words as to the treatment of the different features of the face.

When the forehead is high and broad, no particular attention need be paid to the view taken of it, but should it recede too much, and a side or three-quarter view of the face be wanted, let the outline blend with the background. The same treatment should be resorted to where there is an undue fulness of the upper part—of course in children this is common, and is no defect, but when occurring in the adult is better to be modified.

Very often one brow droops a little, or the eyelid may have the same tendency, in which case I find the best plan to avoid exaggerating this inequality is to turn the figure to that side and the head towards the camera, keeping the droop in the shadow. Variety in noses is endless; make the lens look down at the short, and up at the long, or rather place them in these relations to the lens. If the outline be ungraceful, modify it by more front view. A really good or beautiful nose will be valued by its possessor, and its beauty will be best exhibited by a slight turn of the head; a broad nose is improved by the same treatment and a somewhat sharp light.

The full eye, when light, is difficult to manage, and, if all other conditions are suitable, should be turned away from the light; in fact the greater portion of the face should be in shadow. When the eye, on the contrary, is dark, avoid reflections which show with marked effect on the eyeball. A sunken eye is generally turned towards the light, but I prefer it turned away, and the light diffused with a medium, such as tissue-paper, close to the head.

With reference to the mouth, the chief want felt in photographs is lightness and transparency of shadow, caused by the non-actinic colour of the lips, as where they are brightest, and therefore most beautiful, the photograph gives the reverse effect. A good deal can be done on the negative to rectify this.

No man will succeed to any great extent as a portraitist who does not exercise a constant and intelligent observation on all that affects his sitters. Details that to a careless or unobservant mind might seem too insignificant to pay any attention to, may yet be of the greatest importance. The things which go to make a pleasing portrait in any one instance may be in themselves little matters enough: the turn of the head, one inch this way or that, the raising or lowering of the eyes ever so little, nothing in fact is too small to notice. Let the eye of the operator acquire the habit of taking in his whole sitter. How different is the expression of a lady or gentleman when at their own table, or in the midst of friends on any social occasion. How vastly different from what we see them when about to take the cap off the lens. An active consciousness enters in and deprives the picture of a natural grace and beauty, as well as freedom of expression; the hands very often suffer, losing entirely their natural disposition. When you are thoroughly acquainted with your subject you cannot be deceived by this conscious expression, and you can remind your sitters that they are not looking like themselves. Now, how can this be said or done when ten minutes previously you did not know such a face was in existence? This is the only reason I can give for so many random and missing shots in photographic portraiture. Knowledge of the subject I say is more or less a necessity when the highest results are aimed at. But you may say, How is this knowledge to be obtained? Are photographers to spend a week or a fortnight at their

clients' houses previous to photographing them? Such is impracticable, and certainly in the case of small-sized photographs, photographer and sitters in the majority of instances must be strangers, but my remarks point more to larger photographs direct from life. I consider it risky, I don't say impossible, because it depends on the subject, to take a large direct picture of a person ushered into your presence and out again in the space of twenty minutes. On a first visit a *carte* might be taken, and on a second visit a cabinet, then the large one when you have gained the necessary acquaintance with your sitter's expression. It is a wonderful art, and because it is so greater wonders are expected to come out of it. The stream of its rapid advance is not confined to one channel, but it continually overflows and seeks with eager haste to fields and pastures new.

WILLIAM CROOKE.

ON PRINTING LANTERN PICTURES BY ARTIFICIAL LIGHT ON BROMIDE PLATES FROM NEGATIVES OF VARIOUS SIZES.

[A Communication to the Birmingham Photographic Society.]

THERE can be no question that there is no plan that is so simple for producing transparencies as contact printing, but in this, as in other photographic matters, one method of work will not answer all needs. Reproduction in the camera, using daylight to illuminate the negative, enables the operator to reduce or enlarge in every direction; but the lantern is a winter instrument, and comes in for demand and use during the short days, when even the professional photographer has not enough light to get through his orders. How can the amateur get the needed daylight if photography be only the pursuit in spare time? Besides, there are days in our large towns when what daylight there is is so yellow from smoke or fog as to have little actinic power. These considerations and needs have led me to experiment and test what can be done with artificial light, and I think I have made the way clear for actual work without further experiment. I have not been able by any arrangement of reflected light to get power enough to print negatives of the ordinary density, and have only succeeded by causing the light to be equally dispersed over the negative by a lens, as used in the optical lantern, but the arrangements required are somewhat different to that of the enlarging lantern.

The following is the plan by which I have succeeded best in the production of transparencies.

B is a lamp with a circular wick, which burns petroleum and gives a good body of light. C is a frame for holding the negative, on the opposite side of which is a double convex lens facing the light. D is the camera and lens. All these must be placed in a line, so that the best part of the light, the centre of the condenser, and the lens, are of equal height.

The method of working is as follows: The lamp B is placed at such a distance from the condenser that the rays come to a focus and enter the lens, the negative is then placed in the frame, the focus obtained, and the size of reduction adjusted by moving the camera nearer or further from the condenser and negative. In doing this no attention need be paid to the light properly covering the field, as that cannot be adjusted while the negative is in its place. When the size and focus are obtained, remove the negative, and carefully move the lamp till it illuminates the ground-glass equally all over, by a disc of light free from colour. The negative can then be replaced, and no further adjustment will be needed for any further reproduction of the same size. There is one point that requires attention. The lens used in the camera should be a doublet of about six inch focus (in reproducing $8\frac{1}{2} \times 6\frac{1}{2}$ or smaller sizes), and the stop used must not be a very small one, not less than a half-inch diameter; if a smaller stop is used, an even disc of light is not obtained, but ample definition is obtainable with the sized stop mentioned.

* Concluded from page 105.

In the arrangement described, a single lens is used for the condenser, not because it is better than a double one as is general for such purposes, but because it is quite sufficient for the purpose. Of course a large condenser is both expensive and cumbersome; there is, therefore, no advantage in using a combination if a single lens will answer.

In reproducing lantern pictures from half-plate negatives, the time required on my lantern plates is from two to four minutes, using six inch condenser. For $\frac{1}{2}$ negative, from two to six minutes with a nine inch condenser. In working in this way, it is easy to be developing one picture while exposing another. The condenser must be of such a size that it will cover the plate from corner to corner. The best part of an $8\frac{1}{2} \times 6\frac{1}{2}$ negative will be covered by a nine inch condenser, and a $6\frac{1}{2} \times 4\frac{1}{2}$ by a six inch condenser.

With this arrangement it will be easy to reproduce from half or $\frac{1}{2}$ negatives or any intermediate sizes quite independent of daylight.

A. PUMPHREY.

COLLODIO-CHLORIDE PRINTING.

[Abstract of Paper read before the London and Provincial Photographic Association.]

IN demonstrating this process to you I claim no special merit, but wish to bear testimony to the simplicity of the operations of coating the paper with the emulsion, toning, fixing, and washing the positives, and the beauty of the results attained, as well as increased permanency over albumen prints, as far as my own small experience and few experiments will permit. I wish to raise an exhaustive discussion on its merits, as I am persuaded that sufficient justice has not been done in the case. I believe, moreover, that the working conditions of the process have been altered of late in such a manner as to fully entitle it to the greatest consideration. I shall endeavour to answer the following questions:—1. Is it a process of greater permanency than that in general use? 2. Will it be possible to achieve artistic and pleasing results without expenditure of exceptional skill and great additional labour? 3. The question that possibly may be raised with regard to outlay. This is not a momentous one if it is found possible to answer the first two satisfactory.

Before I go into the question in detail, I must submit that the process, as brought before our notice some years back, was not such as to recommend itself readily to the practical worker. Troubles arose from the peeling of the delicate collodion film, curling of the prints in their moist state, and various other complications, including uncertainties in the toning operations, which made it justly appear a difficult process; but now, thanks to Dr. Liesegang, none of these troubles and uncertainties remain. That it is a very fine process facts show. I employ the process now in the case of customers who do not mind paying a little extra and can appreciate it.

Now with regard to the first question, permanency, I would suggest that if we subjected prints to such a severe test as they are never likely to receive—namely, exposing them in a show-case facing the sun outside of the house during one summer and a succeeding severe winter, and then nail them to a wall of a room where several gas burners are for a few months, and they stood this test, we may venture to call them very much more permanent than albumen prints. I have done this with the favourable result mentioned. Numerous eminent and respectable German firms will testify the same fact, I believe, and Captain Abney says: "In the year 1869 I printed all my negatives by the process. The prints had a beautiful black-brown tone, and some have been exposed to sun and gaslight ever since that period; others are mounted in a scrap-book; and others are loose in a portfolio. Out of the lot not one has altered in colour or purity of the whites. This is what I should have expected theoretically, for there is nothing to cause fading. The organic salt of silver, which has been altered by the light, is not a complex body, but one of definite composition, since it was the citrate of silver which was employed. On fixing the part not reduced, it dissolved out freely, and there is nothing to hold it back in the film, since it consists of collodion, which is essentially porous." The Court photographer, W. Cronenberg, has used nothing else for one and a half years. He says that he has a large quantity of the best albumenised paper left for which he has no use. Of course there are emulsions sold at such low figures as are inconsistent with the good article. It is owing to this fact that many photographers try the process and reject it as not superior to others. Some fail in consequence of their own wisdom, getting hold of or accepting any published formulae from unknown writers, perhaps not even following the instructions closely.

From these and other instances, as well as my own experiments, I venture to maintain that members subjecting well-manipulated collodio-chloride prints, from Dr. Liesegang's or other good emulsions, to before-mentioned tests, they will not detect the slightest

change. Furthermore, to prove that they are much more permanent than albumen prints, I shall immerse the two simultaneously in a solution of cyanide of potassium, not with a view to demonstrate that this solvent has no action, but solely to show that when the albumen print is entirely destroyed the collodio-chloride print is scarcely attacked. From the foregoing I do not think it unreasonable to conclude that the question has been answered satisfactorily.

We will now practically examine the second question, whether we shall be able to obtain artistic and pleasing results without employment of exceptional skill and additional labour. I here submit a number of prints in order that you may examine the depth to which they must be exposed in the printing frame. The time required scarcely equals and certainly does not exceed that of the albumen process. A not very unimportant advantage over albumen prints is the fact that collodio-chloride-paper prints do not expand, and you will note in the demonstration to follow that the great obstacle, curling of the prints in the water, has been entirely removed. With reference to softness and delicacy of the prints, I may mention that by varying the proportions of the chloride employed it is possible and advisable to modify the character of the print, and I believe that Dr. Liesegang supplies separate solutions for the purpose.

Since writing the above, I am very glad to subjoin that having prevailed upon Dr. Liesegang, that gentleman has been kind enough to give me the formula he employs for making the emulsions. It is as follows:—Dissolve 8 grammes (4 drachms 3 grains) nitrate of silver in 5 c.c. (1 drachm 25 minims) hot distilled water; pour this into 200 c.c. (7 ounces 18 minims) alcohol '805; add 12 grammes (3 drachms 3 grains) pyroxyline. After the lapse of half an hour pour to it 250 c.c. (8 ounces 6 drachms 23 minims) ether; shake well. In another bottle dissolve 1 gramme (15 $\frac{1}{2}$ grains) chloride of lithium and 1 gramme (15 $\frac{1}{2}$ grains) tartaric acid in 50 c.c. (1 ounce 6 drachms 5 minims) alcohol. This second solution is poured into the first, agitating the combination well. For vigorous negatives take a little more chloride, as a softer print results from it.

I have made an emulsion by this formula last night in the space of ten minutes, not counting a half hour's interval, and coated a sheet of paper, and obtained some very excellent prints to-day without filtering. I have brought some of the baryta-surfaced paper with me, and shall be pleased to give a sample to members who wish to experiment. I should advise to coat half a sheet at a time or less at first. It is best to coat in a cool room, transferring the sensitised paper to a warmer one, but not to dry by heat. [The speaker here coated a sheet of paper with the collodion emulsion.]

To tone the prints I use Obernetter's toning formula, which can also be used with the gelatino-chloride prints. It is composed of the following:—No. 1. In 35 parts of water dissolve 5 drachms of sulphocyanide of ammonium. No. 2. In 15 drachms of water dissolve 15 grains chloride of gold. Into 100 parts of No. 1 pour 10 parts of No. 2, not *vice versa*. In my own practice I dilute this with an equal quantity of water. As you will observe, their appearance in the toning and following solutions are by no means prepossessing, which as you all know is the case with many things that conceal beauty in some shape or another.

J. HUBERT.

ALBUMEN PAPER.

THROUGH twenty years of practical experience with albumen paper have come in contact with nearly all the ailments connected with its working, and most of this time have looked for some new formula to make better tones, more brilliant whites, and half tones. Year by year I am more convinced that gold, silver, and other material, go but little toward making fine work, but we may profit by the old woman's experience, who said of her good cooking that she seasoned everything with a good deal of good judgment.

Many have made inquiries as to the manner of washing, toning, and fixing albumen prints, but it is so very simple that it seems unnecessary to explain the process. It appears to me that one of the great causes of failure is a desire on the part of many beginners to try to work complicated formulae, thinking the more ingredients they get the better their work will be. In the first place, the tone of a photograph is made in the negative, and whatever the quality of it is so the tone of your print will be. Some say if you use a little of this and more of the other you will get certain tones. I do not believe it. Take a first-class negative and any of the well-known brands of albumen paper, float one minute in a bath containing from forty to sixty grains of nitrate of silver to the ounce of water, according to the temperature. This is the best formula known to me. Then wash your prints in two or three changes of water, just long enough so that the gold will not precipitate the chloride of silver on the print. Then

immerse in water with a small amount of salt, and you are ready for toning. Before commencing to wash your prints make a gold solution as follows:—One grain chloride of gold to eight ounces of water neutralised with any alkali. I use carbonate of soda to make it rather alkali, adding about one teaspoonful of common salt, and you can produce any tone from a rich brown to the finest purple-black.

On the other hand, take a poor negative and use all the means known to the photographer and I have yet to see a first-class tone. All this is supposed to be done when the silver bath is fresh, but after continued use it soon becomes disordered, and this is where the trouble begins. It may become weak, and then the prints come out mealy, and sometimes the paper has a mottled appearance. The way to overcome both these difficulties is to add more silver. After several times strengthening it becomes filled with albumen, and this forms a compound with the nitrate that is apt to soften the albumen, and it slips from the paper when being handled. The only remedy I have found for this is to boil the solution down, fuse, and add new silver, when it will be again ready for use. After fusing a few times, the bath is liable to become alkali and dissolve the albumen from the paper. The addition of enough nitric acid to bring it to a neutral point is all that is needed to make it right for using again.

Care should be taken not to get the bath too strong, as it is liable to give a sunken appearance, showing a mottled look like that produced by a weak one. My experience has taught me to avoid extremes in all things connected with albumen paper—that is, not to have the bath either too weak or too strong, and, by so doing, produce the most brilliant prints. Likewise avoid all kind of dodges recommended for making better prints, as every ingredient added to the mixture soon forms a compound of which you cannot tell the nature.

—*Photographic Times.*

II. McMICALH.

SILVER PRINTING ON ALBUMENISED PAPER.

[A Communication to the Photographic Society of Philadelphia.]

I BELIEVE myself justified in making the assertion that photographic printing has not essentially changed during the last twenty years. If this be true, it might seem to be an easy matter to deduce such principles from the practice of the best operators as would lead to the laying down of fixed rules from which no departure could be made, save at the almost certain penalty of failure in one or another of its forms.

Practical experience in photographic printing, however, as well as a knowledge of the practice of others, would rather teach us that success in this direction is hardly to be obtained by reducing, or attempting to reduce, the matter to scientific principles, but that empiricism (if I may use the word) is both easier and safer. I doubt whether there is a single operation in the whole routine of silver printing that has not been fought over by the advocates of different manners of working, the result being finally left undecided.

Remembering that prints are really a secondary product of photographic manipulation, I think that the reason of this eluding of opinion, to which I have just alluded, may be found in the character of the negatives used, in the paper, and in the whole practical routine or handling. As full consideration of these three factors would be impracticable here, let me generalise my remarks rather than attempt to give rules for working.

As far as we can gather from our knowledge of early practice in silver printing, it seems pretty clear that the fine effect in the print was formerly sought for by using a strongly salted paper, floated on a correspondingly strong silver bath, and used without fuming with ammonia. The negatives were also probably much more intense, or had greater contrast between light and shade. The paper itself was thicker. Inasmuch as it was an expensive matter to work silver baths of from eighty to one hundred grains per ounce, the quantity of soluble chloride in the paper was reduced together with the strength of the silver bath. It had been definitely ascertained that over and above the quantity of nitrate of silver necessary to convert the chloride, a certain excess of silver was indispensably necessary.

As is so often to be remarked when changes take place in scientific practice at large, the pendulum swung so far in the other direction that baths of even twenty to thirty grains per ounce were advised, as well as the addition of other soluble nitrates which were claimed to supply, in part at least, the place of the silver salt. Such ideas are now forgotten, as they well deserve to be. The strength of the bath for ordinary work might be taken at, say, fifty grains per ounce, reducing to forty in hot weather, and perhaps increasing to seventy in cold weather or weak light. I must again beg you to remember that I am here making no attempt at a regular formula.

The failures, arising from disproportionate strength of bath to paper, would be more noticeable in the case of an unduly weak solution. The paper would print slowly, and lose much of its strength and brilliancy in toning and fixing, while the only troubles to be anticipated from too strong a bath would be an increased tendency to discolour (particularly in warm weather), and perhaps to the formation of what are technically known as "tear-drops."

The characteristics of a perfect negative for printing would be difficult

to define closely, even if we had the negatives before us, and, of course, still more so in words. Laying aside all technical imperfections, we can say that the perfect negative is the one that will give a complete scale of tone (or light and shade) in the print, varying from black to white.

Where prints of the finest quality are desired, it is of every importance that they be printed in a light whose actinic power will suit the negative and the paper.

The well-known rule of printing strong negatives in a strong light and weak negatives in a weak one, should always be borne in mind. I have found it better to subdue the great strength of the sun's light by pasting layers of white tissue-paper over the printing frame, in the case of weak negatives, rather than to leave the frame open and print in diffused light. By following this plan, I have often obtained vigorous prints from negatives thin enough to give very effective solar enlargements on albumenised paper. Of course, this is a tedious operation, and I do not by any means advise that negatives should be made so thin as to require this treatment. But, as any landscape photographer who has had experience with the inconstancy of Dame Nature and chemicals will know, the negative does not always turn out just as we might wish. I have also been led to believe that the strength of the light in which the print is made has an influence upon the tone of the print; and let me here remind you of the great law in photography, that a weak light acting for a lengthened time upon photographic tissues gives very different results from a strong one acting for a short time.

The strength of the silver bath I have already spoken of, but let me refer to it again, merely to say that I believe fully in the principle of using weak baths for weak negatives and strong baths for strong ones.

All that can be said about fuming can be summed up when we say that the paper should be *absolutely dry* (heat being used if required) before being subjected to the ammonia, and that the latter should always be as strong as possible. Ten minutes in strong ammonia ought to be enough.

It would perhaps be difficult to answer the question why so much stress has always been laid upon the formula by which the toning bath is made, and it is easy to see how a beginner, taking up the literature of the subject, is involved in great perplexity among the numerous recipes given. The amount of free silver left in the print after the preliminary wash will have a direct influence upon the whole process of toning. The theory was laid down by Hardwich, that no print containing free silver could be successfully toned in alkaline chloride of gold, but it is doubtful whether this is strictly true. When we consider that nitrate of silver has not only a peculiar affinity for gelatino and albumen, and is removed with difficulty from either of these organic substances, it is questionable whether prints supposed to be washed free from silver are so in reality. To get rid of the last traces, we should probably have to soak the print for a long time in a solution of some chloride or other haloid, and it would then be found that the pale brick-red colour so obtained would not tone up to the brilliant, vigorous black or purple. The treatment by the lime bath would seem to help us in sustaining this theory, for excellent results are to be had by simply immersing the print in the toning solution without any preliminary washing whatever. The free chlorine in the lime bath immediately acts on the free silver to a greater or less extent, after which the toning proceeds uniformly even, in spite of the heavy deposit of chloride of silver that forms on the face of the print. To the question, "How much shall the print be washed?" I do not believe that a positive answer can be given. Presupposing good water supply, and ample room in the tanks (a most important thing), it might be said that from ten or fifteen to twenty-five minutes would be about right; the print, of course, not being allowed to stick together in masses. I have seen excellent results obtained by merely soaking the prints a few moments in water which was changed once, and followed by a wash of one ounce of No. 8 acetic acid to every gallon of water; after they had slightly reddened the acid was poured off, and the dish filled up again with plain water. The toning bath was gold with acetate of soda, kept for about twenty-four hours before using.

In the ordinary alkaline toning bath, the presence of too much free silver in the prints will manifest itself by unequal action on the print, meanness, and diagonal red lines. It is a safeguard to have a saturated solution of common salt close at hand, so that a little may be added to the bath if the washing has been insufficient. In such cases, the bath will generally be cloudy from chloride of silver after the prints have been toned. An important practical point is that there should be *white* light enough to enable the change of colour to be distinctly seen. Subdued daylight is best, but gas at night may also be used. I have always judged of the tone by reflected light, that is, by the face of the print; not by looking through the print, as some very successful operators are in the habit of doing. The prints must be well rinsed after toning, and of course it is necessary not to expose them to light more than is absolutely required.

I was much surprised a short time since to learn that it was a common practice not to throw away the hypo fixing bath, but to keep it over from day to day. I mention this only to condemn it; for, although fine results may be made, the tones are probably due to a sulphureting action fatal to the permanence of the print, as well as the risk of imperfect fixation, owing to the bath becoming weaker by use, and losing its solvent properties. I would urge not only that the solution be strong, but that a liberal quantity be made up fresh for each day's use, and that the prints be kept constantly moving, so as to ensure thorough action. If economy must be rigidly observed, it would be better to let the bath after use simply

stand in the dish until strengthened enough by evaporation to fix negatives. Commercial hyposulphite of soda I have never seen show an acid reaction.

The same general ideas as regards washing of prints before toning might hold good in the washing after fixation. That is to say, I believe that too much stress has been laid upon prolonged washing. Rapid change of water, and constant moving of the prints, with every now and then draining off the water completely, ought to finish the process in from two to five hours, according to circumstances. The best safeguards against blisters are to see that the paper is not too very dry before silvering, and to pass the prints from the hypo into a strong solution of common salt. The dish containing them may be set under the tap, and the solution slowly diluted by allowing a small stream to flow in, the washing being afterwards carried out as usual.

Let me now roughly outline a routine of printing which I have myself followed successfully. The room used for the purpose should have a southern exposure. The paper, of course, may be floated anywhere, and the silver bath may be fifty grains to the ounce. My favourite formula contains half an ounce of aqua ammonia to every quart of solution, the brown oxide of silver being taken up again with a few drops of strong solution of nitrate of ammonia. This leaves the bath strongly alkaline, and enough nitric acid should then be added to nearly, but not quite, neutralise it. If a few drops of saturated solution of alum and about ten per cent. of alcohol be added, they will increase the coagulating power of the bath. The paper may be floated the night before in cool weather; and if anything occurs to prevent it from being used on the following day, it should be laid under pressure between sheets of white blotting-paper, previously soaked in a saturated solution of bicarbonate of soda and dried. The paper thus protected will keep good for many days, and, I believe, would give results superior to the ready sensitised paper now so much in vogue. Fuming should not be done until just before printing. The negatives may be sorted over, placing the strong ones and the weak ones together, and having tissue paper, cut to the proper size, ready to paste on the frames, as before alluded to. The various dodges for double printing need not detain us here; but if it be attempted, skill and care will be required. A sufficient quantity of chloride of gold solution, one grain to the drachm of water (stock solution), is measured out, allowing, say, one grain to the sheet. This is carefully neutralised, either with bicarbonate of soda or borax, and allowed to stand while the prints are passed through several changes of water. I have generally used the toning bath at the strength of one grain to five ounces of water, taking care to have the solution lukewarm in winter weather. The bath when ready should be nearly free from the yellow colour of the gold. If the prints tone unevenly, add a pinch of common salt to every ten ounces of bath. The fixing bath may contain an ounce of hypo to six of water in summer, or four in winter, and should be made up with warm water, to compensate for the refrigeration caused by the dissolving of the hypo. The prints may be left in from ten to fifteen minutes.

I would again insist upon having the dishes and washing tanks large enough to accommodate the prints with ease. The paper should be silvered in whole sheets, and very effective dishes for the purpose may be made of wood, protected by paraffine, a hot iron being used to melt it and drive it well into the pores of the wood. Washing tanks might be made in the same way, but porcelain only should be used for toning and fixing. If the water be full of finely-divided mud, it will be necessary to drain the prints well after removal from the wash water, and dabble them about in a gallon or two of well-filtered water, such, in fact, as is used at table.

ELLERSLIE WALLACE.

LIMELIGHT MATTERS.

MR. LEWIS WRIGHT, in his remarks under the above heading, says he should like to know from some one who has practically tried the patent automatic gas regulator for compressed cylinders, if they answer when the taps of jets are turned off. As I have used these valves on oxyhydrogen, triple, and biunial lanterns, and on single lanterns with the oxyether light, it will be interesting to your readers as well as himself to know that they do act perfectly, in fact, a gas cylinder with an automatic valve attached is practically the same as an average weighted gas bag. The light, however, obtained from the cylinder and a mixed gas jet, is far in advance of that obtained from an eight or ten feet gas bag with three or four fifty-six pound weights on. Mr. Wright questioned my figures as regards price of pressure board, and says he was able to get a large size one made for 18s. 6d. The material of a first-class double pressure board with prop (ironwork and wood) cost about £1, and it takes two days to make it properly, so he must have been exceptionally favoured, or lucky, in finding a carpenter to work so cheaply, or if made at a venture, which probably it was, the carpenter had nothing to be thankful for for the order. If prices are quoted, I think it is only fair that they should be commercial, and not what an odd article can be found for. I think Mr. Wright will call to mind that the price of prisms he mentions in his valuable book on *Light* is certainly not commercial if a fair quality is supplied.

The price of the gas when supplied in cylinders is no doubt somewhat prohibitory, but this I have good reason for believing will soon be remedied; for at my (and probably other exhibitors) suggestion the compressor of oxygen will act on my oft-repeated advice and shortly supply ordinary

customers through any optician at 6d. per cubic foot, in quantities of not less than twenty-five feet. When it is considered that the new steel bottles are of less bulk and much lighter weight to hold this quantity than the iron ones that hold fifteen feet, and that the gas does not deteriorate by keeping, it follows that there is no waste if judiciously used, and so an element of economy over the bags is introduced; for it is seldom that one or two feet of gas is not left in the bag after an entertainment. The automatic valves can be set to any pressure by modifying the spring that presses on the indiarubber bellows, but they are generally set to twelve inches water pressure, and the Archimedean screw and valve work so perfectly that the increase when stopcocks are turned off is not more than three inches at the outside, in fact the tubes cannot swell to blow-off, and the difference in pressure due to friction and everything is imperceptible. As a proof of the satisfactory working of the automatic regulators, it may be stated that a customer of Mr. J. H. Steward's had a pair down on trial, and thoroughly tested them in connection with a biunial lantern, and also in comparison with valves made on the principle of steam-engine valves, with lever and weight, and was so pleased with the simplicity of the action and ease of working that he decided to keep them, and use them in preference to the others or bags.

G. R. BAKER.

ART IN AMERICA.

PROFESSOR HERKOMER, A.R.A., Slade Professor of Fine Art at Oxford, when lecturing at Toynbee Hall recently, gave some account of America as seen by an artist's eyes. America has begun her art career with architecture, and, in Professor Herkomer's opinion, this was quite right, architecture being the beginning of all art. Art, however, in the sense of painting has not yet much hold in America, according to the Professor.

"I don't mean," he said, "the possession of pictures. In America they make plenty of money, and if a man fails he can begin again, and does not lose prestige. Art in America is not strong at present. The best work done lately in all the art schools of Europe has been done by American students. At the same time, no painter in America, or very few of them, are happy in America. It will take a long time for art to become a real thing there. It needs infancy; architecture and even sculpture can be taken there, and will grow; but art, in the sense I am talking of, must grow from the beginning. Painters who go there find that art transplanted dies out, or if any keep it alive, in some sort, they have to come perpetually to Europe to nourish it. One reason for this is the want of sympathy between the American patron and the artist. Before the war had run its course, some American landscape painters, who had studied in Europe, painted huge landscapes of the Rocky Mountains and other picturesque parts of America, and they had to paint with the brush in one hand and a revolver in the other. They worked the oracle, and sold these pictures for large sums—£5000 and even £10,000 each. But when Americans began to travel, and found that only £500 or £1000 was paid for big pictures here, and when the railway enabled them to see the Rocky Mountains comfortably, they felt that they had been cheated by these artists. They did not know; they had not time for knowing; so they said, 'We will wait, and not trust any artist but who has an European diploma.' A feeling of that sort is hereditary; I believe a person is born with the suspicions of his forefathers. Dealers have done a great deal of damage to America; so it comes that nine out of ten painters in America cannot get their living without teaching."

About a year ago Professor Herkomer went over there again, and stayed five months, engaged in portrait painting. He never worked for a more appreciative people. He was struck by their power of reading character. It was not respectable to read character here, but it was all the mode there. He painted a trader, now worth a million sterling, formerly a seller of apples in the street, and this man said to him, "You must get my eyes; I trade on them." He painted Jay Gould, and reading character was one secret of that man's success. Professor Herkomer attributed the enterprise, the activity, the go-a-headness of the Americans largely to their climate, dry and electric as it was.

Remarking upon the character of American society, he described it as being as refined as in England, without snobbery. America was going to do the greatest in most things, in art amongst the number. "We have," he said, "an American painter who has brought a strange style into our Academy. By a remarkable accident his picture was hung in a conspicuous place. It was like a fresh breeze coming into the Academy. Some were frightened at it, but most of us welcomed it." The lecturer gave some account of his experiences of portrait painting in the United States, and in conclusion spoke of the reverence of Americans for England, and of the desirability of our learning from them how they learned from us.

A CAMBRIDGE ELECTRIC LIGHT STUDIO.

WE have received from Mr. Valentine Blanchard, jun., Cambridge, the following account of the electric light installation in his studio. As the candle power seems so extraordinary for the motive power, may there not be a mistake by a unit?

"The entrance to the establishment is fitted up with an arc lamp, which

gives a light of about 10,000-candle power, and which brilliantly lights the entrance and thoroughfare for a considerable distance. The reception and dressing rooms are lighted with Swan-Edison incandescent lamps, each of thirty-two-candle power, which give a cheerful and pleasing appearance, and show off the numerous specimens of photography to advantage. The studio is also fitted up with four incandescent lamps of the same candle power, which are used for posing, focussing, &c.

"The large arc lamp for the studio, which gives a light equal to from 30,000 to 40,000 candles, is fitted with a reflector about three feet six inches in diameter, and by a simply contrivance a soft light is diffused upon the sitter, the direct rays of light from the arc being shielded. The dark room is fitted with a Swan-Edison incandescent lamp of eighteen-candle power, screened with ruby fabric, giving an uniform and comfortable light for development. The dynamo is worked by one of Crossley's well-known gas engines, fitted with an electric light governor. Mr. Blanchard finds that six-horse power is sufficient to work all the lamps at one time. By the use of opaque blinds to cover glass of studio, the electric light can be used any time during the day."

CONTINENTAL PHOTOGRAPHY.

[Translations and Abridgments.]

GERMAN AMATEUR AND PROFESSIONAL PHOTOGRAPHERS.

Dr. VOGEL says that a professional photographer has recently written to him about the increasing number of amateurs, and asking if he can do anything to check the augmentation, because it is doing injury to trade; the writer suggested that photographic chemicals and other articles should be sold to amateurs at a higher price. Dr. Vogel replied that he was accustomed to these complaints, and that if they increased, the fact was due to the progress made by amateurs. He spoke of the great advances amateurs had made in photography, and cited by way of example the names of Daguerre, Talbot, Niepce, Archer, Bennett, Wortley, and others. Musical amateurs do no harm to the musical profession, but rather the reverse. Amateurs are not responsible if they exercise an adverse influence upon the business of professional photographers, for that would merely indicate that the latter have not attained the highest photographic skill; the true remedy is to turn out better work. The photographer who is also an artist does not fear the amateur, he knows the limits of the power of most of them; they lack skill and taste in posing models, they commonly make errors in the mode of lighting, and they cannot do skilled retouching. The strength of the amateur, therefore, lies chiefly in dealing with landscapes and architectural subjects, consequently here his competition is felt by the professional, and as a matter of fact the person who complained to Dr. Vogel is a landscape photographer.

Some time ago a Munich architect gave an order which included the photographing of several monuments in Berlin; these photographs were executed by a portrait photographer, but gave no satisfaction to the architect. This came to the knowledge of an amateur who could do such work well, and he received an engagement to take all the required photographs. Dr. Vogel recommends professional photographers to study their work to its roots, to read everything published about photography, and to obtain full knowledge of everything relating to the advance of the art. A professional who had not done these things once heard an amateur talking about photography with the salts of platinum, and exclaimed, "What! Print with platinum! That is not possible or I should have known it!"—*Photographische Notizen*.

ORTHOCHROMATIC PLATES FOR LANDSCAPE WORK.

Dr. Vogel has repeated the experiments made by Obernetter in the photographing of landscapes upon orthochromatic plates, and found the advance upon the results given by ordinary plates to be surprising. When the ordinary negative is examined by itself, all appears to be perfect; all is sharp and every leaf can be seen. But when this is compared with the orthochromatic negative the differences are perceptible. In the latter each tree can be distinguished from its neighbour, consequently there is remarkable relief in the image; the green of the acacia can be perfectly distinguished from the green of the willow, and that of the poplar from that of the oak, where upon the ordinary plate all appears uniformly grey. Unhappily, Obernetter's plates prepared with bromide of silver, azaline, and erythrosine will not keep many days, and his efforts to make them keep have not been attended with good results; the exposure is three times and sometimes four times as long as with ordinary plates.—*Photographische Mittheilungen*.

THE PHOTOGRAPHICO-SCIENTIFIC EXHIBITION AT BERLIN.

In the above Exhibition held at the Academy of Arts of Berlin, were magnificent photographs of the sun by Dr. Lohse, of Potsdam, and Dr. Janssen, of Paris; a photograph of the nebula in the Pleiades discovered by photography; photographs of the planets by Henry, of Paris; stellar spectra by Pickering, of Boston; and, above all, the great solar spectrum of Rowlands, having a total length of thirty-six feet, taken by concave diffraction gratings and extending almost to the sodium line D. The landscapes include among others some remarkable views of America, and of the Yellowstone Park on sheets of fifty centimetres, also some photo-

graphs by Obernetter demonstrating completely the superiority of orthochromatic plates. As for instantaneous views, those of Anschütz are the most striking. There are also photographs of flashes of lightning by Kaiser and by Jacobsen, likewise a photograph of the aurora borealis of Tromholt; there are also the balloon photographs of the Chevalier von Seld, and the moonlight and twilight pictures by Dr. Vogel.—*Photographische Mittheilungen*.

PATENTS COMPLETED.

IMPROVED FORM OF DEVELOPING BATH, ESPECIALLY FOR LARGE PHOTOGRAPHIC PRINTS.

No. 3061. BENJAMIN HOWARTH THWAITE, F.C.S., 37, Victoria-street, Liverpool.—*March 4, 1886.*

My improvement consists in the method of forming and constructing developing baths, especially for large photographic prints, such as copies from engineering drawings.

I make my developing bath in the form of a rectangular receptacle sufficiently deep to hold prints lowered in vertically and end-ways. To make the bath portable I provide wheels on which it can run, I make the lower end or bottom of the bath rather wider than the top, the width I usually adopt is five inches at the bottom of the bath and four inches at the top; by this arrangement I prevent the prints from becoming attached to the sides.

On each side of the bath, close to the top edges, I provide drying rods, attached to the bath by small brackets; under these drying rods I provide drip troughs into which the moisture runs or drops from the prints when they are hung on the drying rods.

I provide draw-off corks to both the drip troughs and the bath.

For ferro-prussiate prints I construct the bath of a framework of wood, lined internally with sheet zinc.

I strongly brace the woodwork together in any ordinary manner, but I usually use hoop iron straps.

For prints in which there is required an acid developing solution, I line the inside of the bath with any acid-resisting material, such as gutta-percha, vulcanite-enamel, or porcelain; if the bath is formed of sheet iron I may enamel it, or I may form the bath entirely of porcelain or earthenware.

In order to assist or facilitate the lowering of the prints into the developing solution, I provide simple clips such as the ordinary letter clips; these I attach to the lower end of the print before lowering it into the solution. For acid solutions I form the clips of vulcanite.

I provide strips of wood, pieces of glass, vulcanite, or wire on which to hang prints when in developing solution.

I may provide a loose cover for covering the upper end of the bath to protect the developing solution.

The advantages of my invention are, that the bath occupies far less space than the present form, and for ferro-prussiate prints the water can be used for weeks without requiring any renewal; as all the salts fall to the bottom of the bath the supernatant water is kept quite clear.

Two or three or more baths can be placed in close proximity when more than one developing solution is required, the whole group occupying very little floor space.

The developing process is much more rapidly effected than with the ordinary flat-bottomed bath.

The claims are:—1. The arrangement of a developing bath, substantially as herein shown and described, for large photographic prints. 2. The use of one or more developing baths placed side by side, substantially as herein shown and described. 3. The combination of said bath with printing frame, substantially as herein shown and described.

IMPROVEMENTS IN OR RELATING TO PHOTOGRAPHIC CAMERAS AND SLIDES OR APPURTENANCES THERE TO.

No. 4179. JOSEPH DAVID WILLIAMS, Station-road, Greenfield, Holywell, Flint.—*March 25, 1886.*

This invention has for its object an improvement in the cameras and appurtenances at present in use, so as to enable the operator to focus and expose without withdrawing any part of the slide proper from the camera, thus obviating one very fruitful source of fogging.

The frame forming the end of the camera has a curved contour, where it rests on the camera bottom so as the more easily to be adjusted. A slide in this frame is formed in two parts, a ground-glass for focussing, and a recess in which is placed a slide or holder carrying the sensitive plate or paper.

A shutter slides laterally in grooves in the sensitive plate slide or holder. It has an attachment at back, which engages with a cross bar or slide. The sensitive plate slide is preferably formed double with two sliding shutters, one on each side. The slide with its shutter (or shutters if a double plate carrier) is fixed in the recess in the frame, and prevented from falling out by movable catches. A stop is provided to prevent the shutter or any part encroaching on the focussing glass. A spring or other stop locks the slide in position. The slide carries the focussing glass, and the sensitive plate holder is supported in the frame between two feathers, and the entire frame is held in position in the

camera by means of an ordinary sliding bracket. A pin on the frame fits into a slot in the bracket. A door at the back of the camera provides for taking out the sensitive plate slide holder, with its shutter or shutters. This consists of a box with shutter for a lid and an opaque back to hold a single plate, or two compartments with an opaque dividing plate between and two sliding shutters. An opaque dividing-piece is hinged between two frames. Two shutters or their equivalent are required for this, one at each side. These are held to it by spring clips or other mechanism, allowing the shutter to slide. The specification is illustrated.

AN IMPROVED PROCESS OF MANUFACTURING ISOCHROMATIC EMULSION PLATES HIGHLY SENSITIVE TO LIGHT.
No. 15,532. Dr. HERMANN WILHELM VOGEL, 124, Kurfürsten-strasse, Berlin.
—November 29, 1886.

My invention relates to an improved process of manufacturing isochromatic gelatine and emulsion and gelatine plates for photographic purposes, and to chemical preparations requisite for such said process.

In the year 1873, I made the discovery that chloride and bromide of silver, which are only sensitive to violet, indigo, and the blue light of the spectrum, can be made sensitive to green, yellow, and red rays by mixing the above-mentioned salts with bodies which absorb the latter rays.

If, for instance, chloride or bromide of silver is mixed with aniline red, which absorbs yellow rays, the chloride or bromide will become sensitive to yellow rays; or if chloride or bromide of silver is mixed with aniline green, which absorbs red rays, the same will be made sensitive to red rays.

I denominated these bodies, which sensitise silver salt in the aforesaid manner, optical sensitizers, and I and others after me have discovered a large number of such optical sensitizers amongst the dyes, and in this manner the so-called isochromatic gelatine plates, coloured with an optical sensitizer such as cyanine, chinoline red, eosine, erythrosine, are now articles of commerce.

All these isochromatic gelatine plates are generally less sensitive than ordinary plates and require a yellow glass plate interposed between the lens and the sensitive plate for diminishing the power of the blue light.

By this interposition of a yellow plate the time of exposure was lengthened, and if the surface of the plate was not quite even, the sharpness of the photograph was lost, so that these isochromatic plates are used on a small scale only for the reproduction of pictures or paintings, but not for portrait or landscape photography.

Now I have succeeded in making isochromatic gelatine plates, the sensitiveness of which is twice as great as that of the ordinary gelatine plates, and which do not require any yellow plate or screen.

This discovery is based—

1. On the application of the eosides of silver, that is, the chemical combinations of eosine dyes with silver. These eosine dyes or derivatives of fluoresceine are all acids, and combine with silver to salts.

2. On the addition of silver salts to other optical sensitizers, for increasing their sensitising power.

As early as 1884, I observed this favourable influence of the presence of silver salts, and proved, for instance, that eoside of silver will give ten times more sensitiveness for yellow light than ordinary eosine, but I have only now succeeded in making plates without fog or film or spots, so that I can introduce the process into practice, and I have proved that it is possible to produce in this manner landscapes and portraits far superior to those taken with ordinary plates.

I have now invented the following methods for making highly sensitive isochromatic plates or sensitising solutions, so that any photographer or amateur can prepare his own isochromatic plates.

In order to attain this object I proceed as follows:—

1. Ordinary gelatine plates are bathed in a solution of a soluble salt of silver (1 : 1000), then in a solution of an eosine dye, or a mixture of eosine dyes, or a mixture of an eosine dye with other optical sensitizers, with or without liquor of ammonia. The solution of the dye can also be used first and the silver solution afterwards, or an emulsion can be mixed with a soluble salt of silver and the dye added to the mixture, or *vice versa*, and with or without ammonia.

2. A silver eoside is formed by mixing a solution of an eosine dye or a mixture of different eosine dyes (for instance, ordinary eosine, blue-tinted eosine, chrysoline, aureoline, phloxine, Bengal rose, or any other derivative of fluoresceine), with a soluble salt of silver, such as sulphate, nitrate, acetate, or fluoride of silver.

This eoside of silver can be collected as a precipitate, washed, and mixed with the emulsion, or dissolved in diluted ammonia or diluted acetic acid, and employed as a bath for soaking dry plates; but I prefer to add liquid ammonia, carbonate of ammonia, or acetic acid, during the process of precipitation, so that the suspended precipitate is dissolved, and to employ the same as sensitising agent for fluid emulsions, or the said solution can be diluted with water and used as a bath for dry plates. The quantity of this solution of eoside of silver to be employed varies according to the quality and kind of emulsion treated with the same, although the following formula will serve as a general guide for those employing my sensitising solution:—

Fifty cubic centimetres of a solution of an eosine dye (one part dye to one thousand parts water or diluted alcohol), one cubic centimetre of a solution of nitrate of silver (one part nitrate of silver to twenty parts of water), one to two cubic centimetres of liquor ammonia.

This solution is either mixed with the emulsion, that is, five to ten per cent. is added to the emulsion, or the same is diluted with two hundred to five hundred cubic centimetres water, and the gelatine plates immersed or soaked in the same for about one minute and then dried.

3. I furthermore use other dyes, known as optical sensitizers, which do not chemically combine with silver, but the sensitiveness of which is much improved by the presence of a soluble salt of silver, such, for instance, as cyanine, chinoline red, coruline, &c., and mix them with any soluble salt of silver. I employ, for instance:—

Fifty cubic centimetres chinoline red, or a mixture of chinoline red and cyanine (solution 1 : 1000), one, five to three cubic centimetres nitrate of silver (solution 1 : 20), fifteen cubic centimetres ammonia liquor.

This solution is employed in the same manner as the eoside of silver solution described under 2.

I furthermore employ the solutions described under 2 and 3 in varying proportion for improving the sensitiveness for any part of the chromatic spectrum.

4. I likewise employ, in like manner as mentioned under 1, 2, 3, the salts of lead which produce, when mixed with an eosine dye, eoside of lead, which said salts can be employed alone or mixed with eoside of silver.

I furthermore employ the insoluble salts of silver, such as the chlorides (tartrates, citrates, &c., dissolved in ammonia or acid).

I do not confine myself to any of the proportions of the mixtures as given in the foregoing specification, as the same can be varied according to requirement, without in any way departing from the nature of my invention.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed, I declare that what I claim is:—1. The application and employment of the chemical combinations of silver or lead, with an eosine dye or eosine dyes, for producing highly-sensitive isochromatic emulsion or gelatine plates, substantially as and for the purpose set forth in the foregoing specification. 2. The application and employment of dyes, known as optical sensitizers, in combination with the salts of silver, substantially as and for the purpose set forth in the foregoing specification. 3. The application and employment of various dyes, as mentioned in claims 1 and 2, in combination with soluble salts of silver, substantially as and for the purpose set forth in the foregoing specification. 4. The manufacture of combinations or solutions of dyes and silver as strong optical sensitizers for colouring gelatine emulsions, or as bath for gelatine plates, substantially as and for the purpose set forth in the foregoing specification. 5. The application of silver salts not soluble in water, but in ammonia or acid, substantially as and for the purpose set forth in the foregoing specification.

NOVELTY IN PHOTOGRAPHIC APPARATUS.

Mr. J. R. GOTZ, of 19, Buckingham-street, Strand, has just patented a new form of portable camera which marks a departure in camera making. The chief feature is the suppression of the slotted stay or fork common to all field cameras. This is replaced by a solid crank or stay fixed as in his previous patent to a pair of sliding pieces running at the sides of the baseboard. By this arrangement and a pair of pinions which engage in a circular rack flanking the camera at both sides, the central swing is obtained and worked by simple pressure with the hand against the lower part of the camera, producing a circular movement of which the upper pivot of the crank is the centre. The other arrangements, such as swing of the front, the disc carrying a sliding lens board by which the lens can be put within any point of the apex of the practically square bellows, and other points of nicety, are all maintained in the new patent.

The folding and setting up of the camera are equally easy of execution, and the facility of bringing the front and back together—practically closed—on the centre of the baseboard without any extension of the latter are points of value.

The accompanying illustration gives a fair idea of the general arrangements.

This patent is destined for whole-plate size and upwards, while the smaller sizes are worked on the old patent described by us a few months ago.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at a meeting of the above Society, held at 5A, Pall Mall East, London, Mr. William England, Vice-President, occupied the chair.

Mr. J. B. SPRUCE exhibited the essential portions of a mechanical device he had made, partly in imitation of apparatus at South Kensington, to vary the size of the openings of a rotating disc, for use with a differential photometer.

Mr. W. K. BURTON said he thought that there was an error in measuring by such means, but he did not like to enter into the matter in the absence of Captain Abney; he thought that the ratio was not the same in the case of contact with a negative and in the case of a distant negative, owing in the latter instance to diffusion from the film.

Mr. W. H. HARRISON exhibited a print from an orthochromatic photograph taken by M. D'Hautov, of Ghent University, upon an ordinary plate and without a coloured screen, simply by waiting until nearly twilight, when the earth's atmosphere had reduced the blue in the light to a greater extent in proportion than the yellow. M. D'Hautov gave twenty minutes' exposure. He had written upon the back of the photograph the particulars relating to the taking thereof.

Mr. SPURGE remarked that as light was reduced contrasts were increased.

Mr. BURTON questioned that statement, for Mr. Spurge was assuming that the exposure was not correspondingly increased; if he were right the whole theory of the action of stops of different sizes was wrong.

Mr. SPURGE was making experiments on the point which were not yet finished.

The question was asked, "What is the best method of washing away the oxalate developer from bromide prints?"

Mr. BURTON added, he always put the developed prints at once into water slightly acidulated with sulphuric acid.

Mr. W. COBB had found the use of distilled instead of ordinary water to be useful in avoiding lime deposits.

Mr. ARNOLD SPILLER believed that a saturated solution of alum with a little acetic acid added would be good.

Mr. BURTON was not aware of any objection to neutralising with weak ammonia after a wash in weak acid.

Mr. FRANCIS COBB thought it to be necessary to do so rather than to put a print charged with weak acid into this sulphate of soda.

Mr. A. MACKIE believed the clearing of developed bromide prints to be the same in principle as the clearing of platinotype prints; the same method should answer for both.

Mr. W. M. ASHMAN asked if pure whites could be obtained with anything but ferrous oxalate.

Mr. SPILLER responded that hydroxylamine, as a developer, gave pure whites. Mr. BURTON said that pyrogallol, carbonate of potash, and sulphite of soda would give pure whites.

Mr. W. E. DEBENHAM exhibited a large negative full of markings of the grain of the tissue paper against which the plate had been packed; he thought that the paper might have been damp, or have contained an impurity; it was the only negative he had taken in which that sitter had not moved, and if any tourist had taken abroad a batch of such large commercial plates, the results would have been seriously disappointing. The plate had perhaps been made three or four months ago.

Mr. W. COBB believed the paper to have been damp.

Mr. J. A. HARRISON thought that there was no doubt upon that point, for the expansion of the paper had been registered on the negative.

Mr. J. TRAILL TAYLOR said that a Philadelphia photographer packed large plates close together with nothing between them.

Mr. BURTON remarked that that was a good plan if they were so fixed as to prevent any rubbing.

Mr. MACKIE mentioned Mr. Dunmore's plan of so placing plates in pairs, with gummed labels at the edges, to prevent them from rubbing.

Mr. W. COBB had found the grass-bleached paper used by silversmiths to perfectly protect plates which he had taken to Rome for use in that city.

The CHAIRMAN had found it capital paper for the purpose.

Mr. FOX SHEW said that grass-bleached paper was of uneven thickness.

Mr. MACKIE questioned whether, in Mr. Debenham's case, the plate had not been damp, and not the paper. He should like to know what was the best intensifier which did not require the application of a second solution.

Mr. DEBENHAM said that bichloride of mercury would do for slight intensification, but care must be taken to stop the action before the whitening stage was reached.

Mr. TAYLOR believed that sulphide of potassium would answer the purpose. He had some films intensified with bichloride of mercury by Disderi about twenty years ago, and they were still as good as ever.

Mr. MACKIE said that Kennett's plan of putting a little sulphate of iron in the fixing bath was good.

Mr. SPILLER said that the action of the sulphate of iron was to reduce some of the hyposulphite of silver in the bath and to throw the metal down upon the image.

Mr. W. COBB stated that by continuing the action of bichloride of mercury too long the image was reduced.

Mr. ASHMAN remarked that one of the annuals stated that if washed negatives were flooded with shellac dissolved in an alkali and then dried they would be well protected during printing. If this were so it was a valuable and important fact.

Mr. MACKIE had tried it and found the negatives not to be proof afterwards against the action of the silver on the printing paper.

Mr. SPILLER said that if ammonia were used to dissolve the shellac it would afterwards go off and leave a waterproof film.

Mr. DEBENHAM stated that if Mr. Wellington's plan of preventing orthochromatic plates from fogging would do for all plates whatever it was a valuable thing. He soaked the plates in bromide and ammonia before developing.

The CHAIRMAN announced that at the next technical meeting the subjects would be bromide prints, and the obtaining of perfectly clear shadows in negatives in difficult cases.

The meeting then broke up.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday, February 17, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. A. Haddon presided.

A letter to Mr. Henderson from Mr. John Stuart, of Glasgow, was read,

enclosing mounts said to injure prints pasted upon them; the dealer had taken many of them back, but the manufacturer was "defiant," saying that they were everything desirable.

Mr. A. L. HENDERSON had boiled pieces of these mounts in distilled water, after which the water but slightly reddened litmus paper, so that there did not appear to be much acid in them from sour paste in the manufacture; he had tested the mounts in other ways, and obtained no adverse results. Of course all the mounts supplied to Mr. Stuart may not have been alike; he wished that the Chairman would test some of the samples sent. He had also received from a provincial photographer some prints with white spots upon them said to be due to bronze powder upon the mounts, and two other photographers who had examined them had come to the same conclusion; he (Mr. Henderson) could find no evidence of any action from the backs of these prints having found its way to the fronts, and through a magnifying glass it looked as if something had been splashed over the face of the prints.

Mr. A. COWAN thought that the paper was thin and had been rolled under very heavy pressure, which had brought out spots where the paper was thinnest.

Mr. W. M. ASHMAN said that the spots might have been caused by bronze, but nothing pointed to that conclusion. Once mysterious spots appeared on the prints of a Norwich photographer, and were found to be due to hypo which had filtered through the floor of the room above and crystallised on the ceiling below, from which disturbance brought it down on the prints as fine dust. The particular spots before the meeting might be due to hypo or to lime.

Mr. W. H. PRESTWICH, in a long experience, had never had spots on prints due to mounts or to any other cause.

Mr. HENDERSON had once been asked to paste the prints on the printed side of his mounts, as the purchaser did not want the prices to appear; in time the bronze printing did its work, and the price of the photograph became visible in white upon its face.

Mr. J. HUBERT then read a paper on printing by collodio-chloride [see page 119], prefacing it by a semi-humorous recitation in rhyme, for which we have no space at present. He followed this by giving a practical demonstration of the various operations.

Mr. J. TRAILL TAYLOR, remarking on the great success with which the demonstration had been given, proposed that all discussion on the subject be adjourned till that day week, which was agreed to.

CAMERA CLUB.

The Thursday evening meeting, February 17, was a members' lantern-slide evening, and some very excellent and unusually interesting subjects were shown.

About one hundred and forty slides were exhibited, of which eighty were by Mr. F. Dunsterville, a visitor at the Club. These made up a series illustrating scenes and manners in India, and comprised characteristic landscape and architecture, interiors and exteriors of Hindoo temples and palaces, studies of detail of the marvellous decorative work on the buildings, and groups and single figures of the natives—hill people, high caste, trading caste, dancing and nautch girls. Notwithstanding the difficulties, and even dangers, presented by the work in India, many of the slides were technically perfect, and, in all, the point of view or study has been most judiciously selected. Altogether Mr. Dunsterville must be congratulated on having a most interesting and valuable collection of negatives and transparencies, one which might with advantage be exhibited again, and which ought to be seen by other societies.

Messrs. Barclay and Mason showed views of the Thames up stream, and each included in his exhibit of views one making a charming picture.

Mr. Sage sent a series of slides representing landscape at and around Bristol and seascapes at Lowestoft.

The exhibition concluded with a selection by Mr. Gale, including picturesque country scenes with figures, also a fine study of barges on the river at Blackfriars Bridge after a snowstorm, in which the result was most artistic, the atmosphere being perfect. Another river scene has been made a most striking picture by the introduction of a magnificent cloud effect.

The subject for Thursday, March 3, will be a full demonstration by the Autotype Company of their carbon printing processes, as shown at their well-known demonstrations at Ealing Dean. Commence at eight p.m. sharp.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

The annual general meeting was held at 181, Aldersgate-street, E.C., on Monday evening, the 21st instant.—Mr. J. Traill Taylor in the chair.

The minutes of the last annual meeting were read and confirmed, and a modification of Rule 3, recommended by the Committee, was adopted. As amended the rule stands as follows:—"Qualification of Members.—Any person connected with photography above the age of sixteen shall be eligible for membership on his or her own application, or on the nomination of a member, subject to the approval of the Committee."

The following were elected members of the Association:—Messrs. H. D. Atkinson, G. L. Addenbrooke, J. J. Briginshaw, C. Bere, E. Clifton, F. W. Cox, S. Casbourne, F. P. Cembrano, W. Dalbyn, J. Davidson, N. Deves, E. Dunmore, W. Few, J. Greathead, J. R. Gotz, H. W. Gorfin, H. M. Hastings, T. Hadlow, F. Hollyer, A. L. Henderson, W. E. Halse, M. J. Higginton, A. J. Higginton, B. Lemere, L. Medland, H. Moul, J. Nesbit, W. H. Prestwich, G. D. Plomer, W. D. Richmond, J. B. Spurge, R. Spurr, H. M. Smith, G. Scamell, J. Spiller, J. M. Smith, W. S. Simpson, J. Traill Taylor, M. L. Troup, J. Urie, W. Willis, R. E. Wilkinson, C. H. Watkins, A. L. Watkins, J. W. Zachusdorf.

The SECRETARY then submitted the report and balance sheet for the year ending December 31, 1886, which showed satisfactory progress. Donations to the amount of £27 15s. 6d. had been received, and the annual benefit at the Photographic Society of Great Britain Exhibition realised £12 12s. 4d. A special lecture given by Mr. A. H. Burton, of New Zealand, produced £4 17s. 9d.; and members' subscriptions, £15 2s. 6d.; this, with £192 0s. 8d. in hand at the commencement of the year, amounts to a total of £252 8s. 9d. The disburse-

ments were £24 7s. The report stated that, notwithstanding the great reduction in the subscription, the large class for whose benefit the Society was founded has not responded to the extent anticipated. Applications for assistance from non-members have been numerous, showing that the reduction of subscription has been a step in the right direction. The members recently elected (over seventy since September last) principally belong to a class unlikely to require aid from the Association, which affords a striking proof of general sympathy with the cause. The Committee solicit the hearty co-operation of all classes of photographic assistants, and wish to bring prominently under their notice the fact that the reduction of subscription necessitates augmenting the numerical strength of the Association at least fourfold. A hope is expressed that the more fortunately situated professional and amateur photographers who have hitherto withheld their patronage will now come forward and impart that impetus to the Association of which it stands in need. The thanks of the members are due to the President and Council of the Photographic Society of Great Britain for the special evening at their Exhibition; to the proprietors of THE BRITISH JOURNAL OF PHOTOGRAPHY, and the *Photographic News*, and others, for their liberal donations; they are also due to Mr. A. H. Burton for his able lecture; and to the photographic journals for their courtesy in publishing the proceedings of the Association.

The report was formally adopted after a discussion in which several members joined.

The election of officers for the ensuing year then took place:—*President*: J. Traill Taylor.—*Trustees*: Captain Abney and W. S. Bird.—*Treasurer*: J. Stuart.—*Auditors*: A. Maekie and J. S. Rolph.—*Secretary*: H. Harland.—*Committee*: W. M. Ashman (*Chairman*), T. J. Collins (*Deputy Chairman*), W. Bedford, F. H. Berry, T. Bolas, J. J. Briginshaw, E. Clifton, H. M. Hastings, J. Hubert, F. Shea, H. M. Smith, J. Zaenlsdorf.

A communication was then read from Rev. A. Tooth, who said, "I shall be glad to express my sympathy and interest in the Photographers' Benevolent Association. We are very much indebted to the men who have worked so successfully and have brought the art to such perfection, and as an amateur I am much indebted for the pleasure I have derived from their enterprise. I suppose it is the intention of your Association to assist photographers who have fallen into distress. I am writing to say that I shall be very pleased to place a vacancy in my Orphanage at the disposal of your Committee for a boy from eight to ten years of age for whom you may be anxious to provide. The boy would be educated under a master, and be clothed. It would be quite free of expense to his friends. He should remain for one year, and at the end of the year you shall be at liberty to ask for an extension of time."

The proceedings terminated with a hearty vote of thanks to the President.

DERBY PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held on February 8 at Mr. Sykes's Restaurant, 33, Victoria-street.—Mr. J. W. Price in the chair.

Upon the question-box being opened it was found to contain a considerable number of questions, the answering and discussion of which occupied the greater part of the evening.

It was decided to have a lantern exhibition on Tuesday, February 15.

A special meeting was held on February 15 for an exhibition of lantern slides, when a large number were shown by Messrs. C. Merry, J. W. Price, T. Hills, J. Dean, T. Scotton, and H. B. Sykes, and a very instructive and pleasant evening was spent.

Mr. E. J. LOVEJOY (Hon. Secretary) announced that there would be a supplementary exhibition at an early date of some slides by Mr. Wellington, of London.

LEEDS PHOTOGRAPHIC SOCIETY.

THE ordinary meeting of this Society was held on the 3rd instant.—Mr. T. W. Thornton, Vice-President, in the chair.

Mr. THOMAS DAWSON read a paper on *The Art Side of Photography*.

Mr. DAWSON began his paper by stating that photography could be practised with very different objects in view. Addressing his audience as practical photographers, the purpose he had in view that night was to bring before them a few considerations on the influence artistic knowledge and imaginative feeling could exercise upon their practice, and the reflex action it would produce. Though photography was undoubtedly a mechanical art, no certainty of mechanical action in its employment could prevent the operator exercising his mind and will so as to modify the result. In that degree, therefore, it was an interpretative art, and as an interpretative art was peculiarly susceptible to the influence of imagination and of artistic skill. It was conceded at once that, with regard to colour, photography ranked infinitely below the art of painting, but in another respect—effect—its claims were exceedingly high. It was in this latter quality, therefore, that the photographer could make manifest his mental powers. By working in conformity with the limitations of his art, and under the formative influence of his artistic spirit, he might hope to produce works conspicuous for imaginative conception. His choice of subject was all-important; and his selective power in that respect was to be cultivated. How? By the training of his artistic faculties, and, above all, of his imagination. It was by no means necessary for a photographer to qualify for the Associateship of the Royal Academy before being able to produce a picture. The kingdom of art was a wide one, and its avenues of approach were many. Books were to be found whose perusal would set the photographer intent upon self-culture in the direction of art upon the right track. Among such were Howard's *Sketcher's Manual*, Tyrwhitt's *Handbook of Pictorial Art*, Tristram Ellis's *Sketching from Nature*, *The Sketcher*, by the Rev. J. Eagles, H. P. Robinson's two little works, and the writings of Ruskin and Hamerton. Conjointly with the perusal of such books as those the study of picture galleries and illustrated books, papers, and magazines should be carried on. Turning to the culture of imagination, Mr. Dawson remarked he could not but be diffident in his remarks upon that topic, inasmuch as upon no less authority than Lord Beaconsfield's, he was addressing one of the most imaginative of audiences. That nobleman had claimed for the English that they are the most imaginative people in the world, because they are the most variously imaginative. Be that as it might, their faculty could not fail to be improved by culture; and to that end nothing was more conducive than the study of our poets, the bards of passion and of mirth, whose immortal pages furnished countless pictures of life and romance. Responding to their stimulating associations, the photographer would find the whole earth teeming with subjects. Tennyson, for instance, was a mine of suggestion for landscape studies. Illustrative quotations from him and other writers

were introduced, and briefly commented upon by the essayist. With regard to the reflex action upon the mind of the photographic artistic student, it was contended the practice of photography would cultivate his artistic faculties, and enable him more readily to perceive latent pictures. The greater scope and power of a photographic lens over the human eye expanded one's mental horizon in like proportion. The photographer gained a comprehensive grasp over landscape scenery, and though extensive views were often far from being the best, a power and mastery over them was not to be despised. One became the better able to appreciate the works of such an artist as Turner, for instance, and no better landscape guide could be found. He was especially of use in respect to one most attractive department of photography—sky-scapes. When one thought of the grand visions of ethereal splendour which had shone in the track of the heavens ever since the morning stars sang together for joy, with what gratitude must one regard the art whose recording power would now and in future prevent the utter loss of the like to mankind! In the combination of skies with landscapes, there would be demands not only upon the technical skill of the photographer, but also upon his knowledge of natural effect, and any efforts he might put forth in that direction would be amply rewarded. Having mentioned the advantage of being able to command a variety of lenses in landscape work, Mr. Dawson concluded by briefly referring to the many fine examples of Mr. H. P. Robinson's skill to be seen in the room, as exemplifying some of his remarks, and being suggestive in many other respects.

The CHAIRMAN commented upon the suggestive character of the paper they had just heard, and invited discussion upon its subject.

Mr. FRANK CURZON was glad to have heard the imagination discoursed upon in Leeds, and more especially in connection with such an art as photography. He wished the members would go so far as to select a subject from Shakespeare, and endeavour to body it forth in the spirit of the great dramatist, though in so doing it might be quite possible to have to go outside Leeds for a Hamlet or an Ophelia. It was not surprising Mr. Dawson had turned to Tennyson for illustrations, because Tennyson's poetry was literally photographic—a kind of mosaic patchwork. He was afraid the influence of photography on art was not wholly happy, because it seemed likely to make people admire pictures which were simply mechanical. It would be a bad day for art when Alma-Tadema was preferred to Raphael.

Dr. JACOBS concurred in the spirit of the paper which had been read to them that evening, and agreed with the author with respect to the convenience and advantage of having various kinds of lenses at command. When travelling in Switzerland last year he had found the benefit of taking four lenses with him. The amateur had a great advantage over the professional photographer, in being able to invest his subjects with artistic attraction. Nothing had struck him as more pitiable than the fate of the professional man, doomed to photograph such miserable-looking specimens of humanity as daily presented themselves before him—generally incarnations of ugliness.

Mr. BOTHAMLEY thought the subject had been very ably treated. He had several of the works which had been recommended to them; they might, however, indulge in too much reading, and it was desirable to get into practice as soon as possible. He was reminded of the Frenchman's saying about photography being to the scientist a science, to the artist an art, and to the commercialist an industry. A concise chapter on art photography would be found in Captain Abney's work, published by Longmans; the chapter was headed "The Picture," and was, he understood, the joint production of Captain Abney and Mr. H. P. Robinson; but whatever art taste they brought to their work, they would find much remained to be done in development.

The collection of pictures kindly lent by Mr. H. P. Robinson were much admired by the members, being fine examples of artistic photography and illustrative of the introduction of figures into pictures.

Mr. THORNTON, of Manchester, exhibited and explained Thornton's "Jubilee" camera and stand.

The meeting closed with an exhibition of lantern slides specially selected by Mr. Dawson for their artistic qualities.

The next meeting of the Society will be held in the Library of the Philosophical Hall on Thursday evening next, March 3, at eight p.m., when a paper will be read by Mr. S. A. Warburton, on *Gelatino-Bromide Emulsion and Plate Making*, with practical illustrations.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

AN ordinary meeting of this Society was held on Wednesday evening, February 16, at the Greyhound Hotel, Dulwich.—Mr. Crossthwaite in the chair.

After the usual business, which was curtailed as much as possible, a number of lantern slides made by members of the Society were exhibited. The lantern was lent and manipulated by Mr. Harold Senior (the Hon. Secretary). Slides made by Messrs. Wolff, Crossthwaite, Ince, and Senior, were shown, most of them being remarkably good. Mr. Wolff's slides were fine specimens of camera reductions on the new chloro-bromide plates. Those by Mr. Ince were worthy of note as being examples of good transparencies produced on Hford bromide plates.

The next meeting of this Society will take place on Wednesday, March 2.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held at the rooms, 36, George-street, on Thursday, February 10, 1887.—Mr. Allan Garnett, Vice-President, in the chair.

The minutes of the previous meeting were read and passed.

The CHAIRMAN announced that at the Council meeting it had been resolved to rescind the resolution passed at a previous Council meeting, "That the Society do not apply for space at the Royal Jubilee Exhibition," and that, on the motion of Mr. Grestorex, seconded by Mr. Atherton, it was resolved, "That the Society apply for five hundred square feet of space in the Photographic Section of the Exhibition."

This statement met with the manifest approval of the members, and was supported by Messrs. Heywood, Brothers, Ford, Leader Williams, the Chairman (Allan Garnett), Schofield, the Hon. Secretary, and others.

The CHAIRMAN said most of the members who had already applied for space as individual exhibitors had consented to withdraw their application and

incorporate with the Society's exhibits. The Chairman also explained there was no compulsion in the matter, for any member who felt so disposed could exhibit individually if so inclined.

The ballot was taken for Mr. Alan Beckett, who was duly elected a member of the Society.

Mr. S. HERBERT FRY, of Kingston-on-Thames, then read a most interesting communication on *Bromide Paper Printing*, describing the details from beginning to end, both for contact printing and for enlarging purposes, the best developers for certain subjects, &c., with the reasons why; and also touched upon the many difficulties that were likely to occur and how to avoid and correct them. Mr. Fry then proceeded to give a practical demonstration by exposing a sheet of argentotype paper under a negative, using a printing frame made to move, so that six exposures from the one negative could be made on the one slip of paper (which was about twenty-four inches long); the time of exposure was varied in order to demonstrate the difference between over, correct, and under exposure. The development was conducted before the members, and the result was highly satisfactory. Mr. Fry then passed round for acceptance by the members some sample packets of argentotype paper, and exhibited a large and fine collection of finished and framed pictures; and, lastly, he introduced some lenses made by Messrs. J. & R. Beck with "Iris" diaphragms. These, he said, had been made by Messrs. Beck for many years, but they had not pushed the sale of them in this country until recently.

After the usual vote of thanks to Mr. Fry the meeting was adjourned at a late hour.

At the next meeting, March 10, 1887, there will be an exhibition of members' work for the selection of a presentation picture to be given to each member, the picture to be enlarged to about 24x18 and printed in either autotype or platinotype.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of this Association was held on the 15th instant.

The minutes of the previous meeting were read and approved, and Messrs. Edward Rodger and D. McCorkindale, M.D., were elected members.

THE PRESIDENT, Mr. P. Falconer, gave an interesting demonstration of the preparation and development of collodion dry plates by the Fothergill process (Hannaford's modification). The plates are sensitised in the bath as for the wet process, then thoroughly washed and flowed with a "preservative" of albumen, silver nitrate, and ammonia, again washed, and finally dried. These plates were originally developed with acid silver and pyro, and were somewhat slower than wet plates. Mr. Falconer has found that when prepared with highly-bromised collodion they can be developed with alkaline pyro, and the very faint image thus produced may be intensified as required with acid silver and pyro. When thus treated the plates are about ten times the rapidity of wet plates. Mr. Falconer used these plates twenty-six years ago, and both in this country and in New Zealand found them reliable. Transparencies of excellent colour were afterwards thrown on the screen, showing the adaptability of the plates for lantern work.

Some fine examples of printing on Eastman's bromide paper by M. Nadar, of Paris, were handed round, and Tyler's patent metallic dark slide was exhibited.

A proposal to enlarge the premises of the Association was favourably entertained, and the Council was empowered to take action in the matter.

A letter from the local Secretary of the coming Convention was laid before the meeting, but the matter was held over for a month, when it will be more evident how the Association can best assist.

Correspondence.

12P Correspondents should never write on both sides of the paper.

THE DISCOVERY OF THE PHOTOGRAPHIC USE OF EOSINE.

To the Editors.

GENTLEMEN,—I observe that in several letters in recent numbers of THE BRITISH JOURNAL OF PHOTOGRAPHY reference has been made to me as discoverer of the properties of eosine as a colour sensitiser for orthochromatic plates. It may be as well, therefore, to state that I cannot consider myself to have any claim in connection with the practical use of eosine as a colour sensitiser in the preparation of so-called iso or orthochromatic plates.

I believe I was the first to experiment in 1875 with the dye in this direction, and to discover that bromo-iodised or bromised collodion plates—wet or dry—stained with it were very much more sensitive to the green and yellow rays of the solar spectrum than unstained plates. This discovery naturally led me to experiment with the stained collodion plates in photographing coloured objects and landscapes, but I failed to produce the desired results. Other important work prevented my following up the research, either with collodion or gelatine plates, and it was left for others to work out the discovery in these directions and turn it to really practical account.

From the information I have at hand, I believe the first to practically apply eosine in collodion plates were the brothers Ducos du Hauron, and in gelatine work Messrs. Attout Tailfer & Clayton, whose plates have been in the market for some years, and successfully fulfil all requirements. These gentlemen are, I think, fairly entitled to all credit and substantial benefit in the way of patents they can legally claim.—I am, yours, &c.,

J. WATERHOUSE, Lieut.-Colonel, B.S.C.
Survey of India Office, Calcutta, February 1, 1887.

ORTHOCHROMATIC PHOTOGRAPHY.—ETHOXO LIGHT.

To the Editors.

GENTLEMEN,—In your issue of January 28, page 51, I find the following: "The employment of eosine and chlorophyl, also colour screens, in connection with photographing colours, was practised more than ten years ago." Now this is literally true, but as such an unqualified statement might appear to some to reflect upon my claims to original discovery in this direction, permit me to state the following additional facts: First. Chlorophyl was never used with wet collodion emulsion plates and a yellow colour screen until I discovered that in that way it was possible to photograph all colours in approximately the true proportion of their brightness. Second. Previous to my discovery no photograph was made, and it was not known that any photograph could be made, in which all colours were reproduced in correct colour tone. Third. Chlorophyl and eosine were never used together (in the same sensitive film) until I discovered and published the advantages of such a combination.

Also, on page 52, Mr. Brooks, speaking of that form of ether saturator invented by myself, says: "These saturators . . . I do not think sufficient to last for an evening," &c. I am pleased to know that Mr. Brooks can suggest no other objection to this invention, because it is a known fact that a good many professional exhibitors in this country are using it, and giving exhibitions of two hours' duration, with a most brilliant light, without experiencing any such difficulty. This light has been used in illustrating most of the Franklin Institute lectures for several months past, and a saturator one-third smaller than the smallest that is sold here has been run two hours, producing a light fully equal to that previously obtained with the mixed gases. Safety jets were not used, yet the flame has never once "snapped" in the jet. It would appear that the imitation saturators sold in England are not properly constructed. It seems to me unfortunate that any one should be led to continue the use of the dangerous Broughton saturator because they are deceived as to the success of the only ether saturator that any dealer in this country dares to recommend.—I am, yours, &c.,

FRED. E. IVES.

2609, Jessup-street, Philadelphia, February 11, 1887.

GENTLEMEN,—Referring to Messrs. Edwards' letter in your last issue, I would point out that in my paper at the Conference I said, "I am quite sure that I am not alone in thinking that had Messrs. Dixon not issued their successful plates we would never have heard so much of the Tailfer patent, nor would the gentleman have bought the English interest in it."

Now the only statement which the foregoing contains is in these words, "I am quite sure I am not alone in thinking;" and if Messrs. Edwards had been present they would have been thoroughly convinced of its truth by the way in which it was received.

If, however, Messrs. B. J. Edwards & Co. want a statement, I can state, with all truth, that up to the time of writing no transfer of the patent has been recognised nor exists in the Patent Office.

They next object to my assertion as to the orthochromatic effect of their plates without a screen. Now, my assertion included all orthochromatic plates, except collodio-bromide. I did not specially single out Edwards's plates. And I have seen no reason why I should withdraw that assertion.

My experiments were carefully carried out in order to find out the full capabilities of orthochromatic plates with and without the coloured screen.

In conclusion, I would say that most people find a difference between practical results and mere results for advertisement.—I am, yours, &c.,

WM. H. HYSLOP.

WHAT CONSTITUTES DISTORTION IN PHOTOGRAPHS?

To the Editors.

GENTLEMEN,—I could not help thinking, when at the last meeting of the North London Photographic Society, that, although the subject must be well known by experts, there is a good deal of misunderstanding as to what constitutes distortion in a photograph. Some pictures are very unpleasant and unsatisfactory when hung up on a wall and seen from a considerable distance, but if looked at from the proper point of sight, every part assumes, as if by magic, its proper form and position, and all distortion disappears—the reason being that there is only one point from which a correctly drawn perspective view can be seen correctly; and I have seen on old engravings a cross about the middle of the picture with a scroll stating that at so many inches perpendicularly above that mark the proper view will be seen. The camera, with a proper lens, must give true perspective, and the picture taken with it must be true if looked at properly, namely, at the exact distance of the focal length of the lens. Unfortunately, that is sometimes much less than is required by the eye, and in many cases only people who are shortsighted, as myself, can see the picture in anything like its true proportions. It would be a great advantage to the apparent correctness of architectural photographs if they could be taken with a lens of not less than twelve inches focal length, and even then they should be looked at, for correct effect, with one eye directly opposite the centre. Any indication of the true horizon shows the proper height at which the eye should be placed.

I was struck the other day with the apparently much distorted appearance of the Clock Tower in a published view of the Houses of Parliament;

but when I looked at it with my short-focus eye, from a proper position, the Tower assumed its proper form and was very beautiful.—I am, yours, &c.,

GEORGE H. SLIGHT.

413, East India Dock-road, February 19, 1887.

ON PRINTING-IN CLOUDS IN PLATINOTYPE.

To the Editors.

GENTLEMEN,—In a recent issue of your JOURNAL, "Monitor" touches upon the "printing-in" of skies upon platinotype prints.

Now, while not intending to write oracularly upon the subject, I think (*pace* "disinterested amateurs!") I may lay claim to know something about the subject, seeing that I am commonly considered a fairly successful platinotype printer. This being so, and as "Monitor" writes that the subject "will bear ventilation," perhaps a few suggestions from me may be acceptable to some of your readers.

It will serve to show that the difficulties to be encountered cannot be very great if I say that my printing occupies perhaps as much as a week, sometimes less, in the whole year; hence it cannot be said that my "hand is kept in" by constant practice. I print very much less than the majority of amateurs.

Another point I would mention is that while I have relied solely upon judgment, as when exposing for a negative, Mr. Willis has a plan by which he hits off the exposures to a nicety; it is an "actinometer" method, the details of which I do not quite remember. I shall, therefore, confine myself to my very elementary method. But, in addition to correct exposure, there is the question of so shaping and graduating the clouds that the effect may be artistic.

To proceed:—I first provide a print "in the rough." With this I select a sky from a series of cloud negatives. If I wish to make several prints alike, while the print is held "against the light" in a suitable position on the negative, small strips of gummed paper—perhaps two at right angles—are fixed on the back of the negative to mark the points where the hard edge of the rebate mark shows upon the rough print (and as it will also show upon the undeveloped print). This hard edge is visible on any print (it being the margin of the picture) when held behind the cloud negative, the whole being viewed by transmitted light. Hence, any subsequent print can be readily fitted in the same position to the fraction of an inch, as was the first print with which the selection was made. I hope I am clear so far.

As regards printing frame, I would not use any ordinary ones except those with glass fronts, and of a size, perhaps, whole-plate or 10×8 for half-plate prints. I have nothing special in this way, though in various ways something good might be turned out.

Having fitted the undeveloped print in right position on the cloud negative, both are carefully placed on the glass of the larger printing frame, and the whole secured as usual, the rubber pad on no account being omitted. A piece of brown paper doubled, or other opaque body—as a piece of coloured felt—is placed over the face of the frame and the whole is carried into the open air. Now come the questions how long to expose, and, secondly, what parts are to receive the impact of light.

To dispose of the first question a little previous knowledge is required of the printing qualities of the negative, or of others somewhat like it in intensity or in density. This faculty of judging is quickly cultivated, as is that of making exposure of plates in the camera; but, of course, various actinometer methods may be employed by those not possessed of sufficiently close observation.

Having decided this point, the frame is conveniently placed, the rough print in front beyond the frame, and the watch by the side. It may serve as a weight to prevent the print being blown away. The opaque material is then drawn off the sky portion, and as the sky-line is generally by no means a straight line, a cloth, which may be opaque or not as preferred, is then roughly adjusted to cover the landscape and parts of trees, &c., to the sky-line. Sometimes a piece of brown paper, roughly torn to shape, may turn out useful in addition to the cloth; indeed, I prefer not to depend entirely upon the cloth.

Well, the adjustment to the lines of the rough landscape is made as well as the eye suggests, and to this end the white gummed paper strips before mentioned will also be found useful. And now it is a little difficult to say what should be done. One thing is certain, use your brains and artistic faculties; but, of course, this applies equally to silver printing. And I may add, bring any amount of intelligence to bear, but, in a sense, do not be too careful. Absolutely accurate adjustments are worse than useless, even if possible. In any case the cloth must be rearranged in various forms during the printing, and the watch is an aid to doing this judiciously—so much to this part and so much to that part; by this means, also, the artistic quality of the sky negative may be practically enhanced.

It is well to provide a few small weights to hold the masks and cloth in position, but the cloth should rarely be held down close to the glass (unless the glass is very thick) by such means; on the contrary the cloth should be in folds, presenting a rounded edge.

When the exposure is judged sufficient, nothing as a rule remains but to develop it; only storm clouds are visible to the average eye, so that clouds which are visible are usually over printed—at least for a hot bath of potassic oxalate.

I find printing as easy as I did that with albumenised silver paper.

Some of the prints in exhibitions are the only ones attempted of the subject.

It remains to be said that as the sky-line of an undeveloped print is commonly visible, the adjustment to the cloud negative may be made without having recourse to the "rough" print, and if the sky-line should not be visible, then the lines of the rebate marks are useful guides, and in some instances I have found that little holes, pierced by one of the legs of a pair of compasses in the margin of the print where the sky-line "runs out" on both sides, useful for purposes of adjustment. The points at which to pierce these are discovered by setting the compasses against the sides of the landscape negative or of a print from it, the lower leg being placed on the "rebate line," and the upper, of course, where the sky-line runs out. These little holes form luminous points by transmitted light. I say this forms a plan by which printing-in skies in platinotype is as easy as other photographic operations. I know that many do not print in skies, simply because they have never tried to do so. There is generally nothing wonderful, nor "hankey-pankey," in the methods of practical men, but they just try.

If your readers should take an interest in the subject, I may be able to give some details of Mr. Willis's plan; but I make no promise in that connection.

It is advisable that the cloud negatives be very clean and not very dense. To obtain the right kind use about three or four grains of pyro and one minim of ammonia and do not be in a hurry. If sulpho-pyrogallol be used the negatives are much like wet-plate ones, and those who print in clouds are aware how the latter facilitate the operation.

If conveniences exist it is an excellent plan to make the cloud negatives on larger plates than have been used for the landscapes. The operation will be found rather easier, and a stock of negatives will certainly provide for a larger number of pictures. Seeing, however, that clouds are often required at one side of a picture, the other side being occupied by more or less solid objects, it follows that the print may project on one side beyond the limits of the cloud negative. It will generally be found a sufficient and satisfactory plan to "sun down" the projecting part (if there are lights through the trees) after the clouds have been printed.

There is one little dodge I sometimes bring into use in development. It is well known—or ought to be well known—to workers in platinotype that it is the deepest parts of the print which suffer most, in a technical sense, from curtailed development; it therefore follows that such parts as clouds will not suffer much in quality, but only in depth, by earlier removal from the oxalate bath than that of the rest of the print. Sometimes, therefore, I lay the cloud side, or corner, down last and then pick it up first; or if I do not raise the part entirely I "take a peep" at it. But do not let me be misunderstood; I do not hold with "taking peeps" at the shadow part of prints, because the result is a "cool" development, and I hope my readers are fully conversant with the various ways in which "cool development" spoils the "blacks" and introduces defects of various kinds.

On the subject of hot and cool baths I may have occasion to write later on, if the Editors think the subject of interest. In the meantime, readers cannot do better, as a rule, than to work with baths not lower than 140° Fahr. for "A" paper, and not lower than 155° Fahr. for "B" and "C" papers.

On the subject of the alleged accelerating effect of common salt on a dry plate, I think it is possible that the formation of magnesium hydrate may have to do with it. Several years ago I found that sulphate of magnesium, used in the alkaline (ammonia) developer, resulted in somewhat similar manner to calcium hydrate—a very black image. This I doubted not resulted from formation of magnesian hydrate. But, of course, that can only apply to the ammonia and not to the iron developer.—I am, yours, &c.,

HERBERT B. BERKELEY.

February 5, 1887.

THE OXYHYDROGEN JET.

To the Editors.

GENTLEMEN,—I hope that Mr. Wright does not imagine that I claim any connection with, or credit for, any part of the fine oxyhydrogen jet I lately got from Messrs. Newton. So far as the illumination or lime turning arrangement is concerned, I had nothing to do with the angle nor the shape of the nozzle and the nipple, nor with the mixing chamber. Having myself made experiments upon the angle of impact (in course of which experiments I broke one nipple and frightened another), I saw at once the advantage of the nozzle shown to me by Mr. Newton, and bought the jet. I am well aware, and Mr. Newton frankly stated, that Mr. Wright had been instrumental in fixing the angle, calibre, and shape of the nozzle; my instructions to Mr. Newton were to adapt my "cut-off" arrangement to a jet such as he showed me. I am pleased and flattered by Mr. Wright's approval of the only part of the jet that I have any claim for suggesting.

The quick pitch of the lime pin is due, I am told, to Mr. Place, of Birmingham, and a great advantage I find it.

Mr. Wright is probably correct when he says that the straighter jet nozzle will "pit" the lime with great pressure, but I fancy the pit will be in a different direction as regards its axis, and less dangerous for the condenser. I must say that as yet, with my usual pressure of one hundredweight on seven feet bags, I have not found a lime "pitted"

worn away it has been undoubtedly, but not into a "pit" with steep sides, like a "pit" made by a jet impinging more "straight on."

Re Mr. Berkeley.—Regarding Mr. H. B. Berkeley's laconic comment on my letter of ancient date, I can only say that when I start a paper factory, or when the Esk comes down in a flood of ink, I may try to reply at full length to his pleasantries. One moral I draw from his letter, that is, that I must take from Mr. Berkeley a course of lessons in negative making.—I am, yours, &c.,

ANDREW PRINOLE.

Craigcleugh, February 21, 1887.

FOG VERSUS ACCELERATOR.

To the Editors.

GENTLEMEN,—“Monitor” has quite misunderstood my motive in sending the two plates to the London and Provincial Photographic Association. I was not advancing any new theory, merely anxious to corroborate a fact that plates are affected by the paper used to separate the films in packing; my experience was that instead of producing fog the paper I used had an accelerating effect. This I think was most conclusively proved, as the paper was not nearly as large as the plate, and where the paper was in contact there was a most distinct effect. The object of the second plate was merely to show that the plates before repacking were perfect.

Where paper is used for separating the films the whole of the plate is covered, and no marks are observed on the finished negative. Whilst on this subject I may as well repeat what I stated in my American notes. I had my stock of plates packed with *papier Joseph*, which I used in repacking, and I had not an instance of a defect although twelve months elapsed from the making and developing of the plates, which were often used under very varying conditions of heat, damp, and intense cold.—I am, yours, &c.,

F. YONK.

February 18, 1887.

A SUGGESTION.

To the Editors.

GENTLEMEN,—Of course there is no reason why some means may not ultimately be found by which the keeping qualities of “Ortho” or “Isochromatic” plates may be greatly improved. Under present conditions it is impossible that their sale, and consequently use, can be very extensive.

Why does not Mr. Edwards supply the necessary solutions made up in bottles, sufficient, say, to bathe one dozen plates? If he only sold so much solution on condition that so many dozen plates were taken as well, he would lose nothing and speedily increase the number of his customers.—I am, yours, &c.,

H. A. LEWIS.

Binsted, Arundel, February 17, 1887.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

William Usherwood, 32, High-street, Dorking.—“Derby Race,” 1886.
Alfred Rogers, Mount Pleasant, Bacup.—“Photograph of Bacup Handbell Players.”
Alfred Seaman, Corporation-street, Chesterfield.—“Eight Photographs of ‘The Ceremony of Reading the Charter of Incorporation of the Borough of Ilkerton.’”

AN AMATEUR (Weybridge).—See answer given last week.

C. STEPHENS.—We shall be glad to see you when you are next in London.

ROCK.—Paint your rocks with burnt umber mixed with turpentine and linseed oil, using the former in excess.

H. J. S.—Apply to the manufacturers of machinery for making paper-hangings. They will probably supply what you require.

Z. Y. X.—The bottle was in splinters when received, and the contents doubtless distributed among the letters in the mail bag.

I. J. S. C.—You will find plenty of formulae in the ALMANACS for the last few years. Any of these will serve your purpose if you give the emulsion a generous cooking.

A. FREEMAN inquires: “What would you recommend me to use as sizing to prepare silver prints for taking oil colours?”—Give it a thin coating of gelatine and gum arabic.

GREENHORNE.—1. $\frac{1}{2}$ means that the aperture in the diaphragm is one-twelfth the focus of the lens. 2. If the lantern lenses are portrait combinations, they may be employed in photography just as they are; but, if single, then must a diaphragm be adapted for them. Send us a drawing.

HY. E. WHITE (whom we welcome back to photography) desires information concerning Mr. Coventry's machine for coating plates, partly described in last ALMANAC, where it can be obtained, and whether it is practically a success. We invite a reply from such of our readers as are in a position to answer.

E. DODGE.—The plan of “restoring” photographs referred to is that of treating them with a dilute solution of bichloride of mercury. The effect of this is that the yellowness of the print is removed; but it must be understood that none of the detail which has disappeared will be restored by this treatment.

P. O. MALLON says an illustrated paper has copied one of his photographs—a copyright one—without asking his permission or acknowledging him as the photographer. He asks if he has any remedy.—If the photograph pirated is a copyright one our correspondent certainly has a remedy under the Copyright Act, and he should take proceedings at once.

BROMIDE.—The precipitation was no doubt caused by the emulsion not being sufficiently shaken between the additions of the silver solution. Emulsify with a slight excess of silver. You cannot do better than follow the directions given by Mr. Wellington a few weeks ago. The emulsion by his formula is specially suited for the production of lantern transparencies of the tone you desire.

R. C. Y. complains that in his attempts at stannotype printing he cannot get the gelatine relief to develop, although, he says, the water used in some instances was nearly boiling. He asks the cause.—The cause is that the gelatine has become insoluble, either from an unsuitable kind of gelatine for the purpose being employed or from its being dried too slowly. Probably the insolubility is due to the latter cause.

C. NASH has some engravings to copy of large size, and asks which is the better plan—to take small negatives with a portrait lens and then enlarge them, or to take them the full size with a long-focus rapid symmetrical he has, adding that the former plan would be the more convenient, as the work has to be done away from home.—By far the better plan will be to take the negatives the full size direct with the symmetrical lens.

LUX says: “Will you kindly say in next issue in reply to queries: 1. Is Alpha paper a film of bromide or chloride of silver, or a combination?—2. Why should it require a gold toning bath when bromide prints do not?—3. Why should a longer exposure and weaker developer produce the red tones, when a short exposure and strong developer yield black tones, as in bromide films?”—In reply: 1. The formula is a trade secret.—2. To obtain the warm tone, toning with gold is necessary. If black tones are preferred, bromide paper should be used in preference.—3. It is a fact that it does so, and with that we must be content.

W. C. B. writes: “Will you kindly enlighten me a little as to the following small worry: is there any recognised rule as to the exhibition, in outside show-cases, of portraits taken in the ordinary course of business? Some people object to what they term being ‘stuck up’ in a show case; but a photographer cannot be expected to be always changing his specimens merely to suit whims and fancies.”—The only recognised rule amongst respectable photographers is never to exhibit any sitter's portrait, taken in the ordinary course of business, without first obtaining permission. It is as unwise as it is impolitic ever to do such a thing.

J. COCKBURN writes: “In photo-micrography, using a camera, how can I tell the exact amplification? Given that the magnifying power of objective and ocular is known, and also the distance from ocular to focussing screen of camera. I am engaged in photographing bacilli, and wish to be able to calculate the number of diameters of enlargement, without using either stage or eye-piece micrometers. I hope to send shortly, for your inspection, some photo-micrographs of the structure of the eye, which I have done by the method I use, and which you printed about two years ago.”—We have among our readers several photo-micrographic experts from whom we should be glad to hear in reference to this matter.

HALLAM writes as follows: “I have some Daguerreotypes of departed friends which have faded, and I have been told that they can be restored; will you kindly tell me how? If they cannot be restored, please say the best plan for an amateur to copy them.”—Faded, or rather tarnished, Daguerreotypes are cleaned in the following manner:—Take the picture out of its frame or case and carefully remove the paper by which the edges were secured, then immerse it in a solution of cyanide of potassium—ten grains to the ounce—until the tarnish has disappeared; then remove and copiously wash under the tap, and finally rinse with distilled water. The plate must then be dried over a spirit lamp, taking care that the heat is applied first at the corner opposite the one from which the water was drained, and then gradually downward over the plate. Unless this precaution be taken wavy marks will be produced in the drying.

PHOTOGRAPHIC CLUB, Anderton's Hotel, Fleet-street, E.C.—The subject for discussion at the next meeting of this Club, Wednesday, March 2, 1887, will be on *Cameras*.

NORTH LONDON PHOTOGRAPHIC ASSOCIATION.—The next meeting will be held in Myddelton Hall, Upper-street, on Tuesday next, March 1, at eight p.m., when the adjourned discussion on lenses will be resumed, followed by a lantern exhibition. All are invited.

FROM Dr. Liesegang we have received a sample packet of his Aristotype paper which we have tried with complete success. The paper is prepared with a collodio-chloride of silver emulsion, and the toning is effected by the sulpho-cyanide bath.

We are sorry to learn of the sudden death of Mr. Charles Harris, which took place at his residence near Manchester on Sunday last. He was a member of the Manchester and Glossop Dale Photographic Societies, and during his travels abroad had made a large collection of photographs.

COLOURS FOR TRANSPARENCIES.—We have received from Messrs. Reeves & Sons, London, a very compact box containing a complete outfit for colouring lantern transparencies. It contains twelve tubes of pigments, with brushes, and everything that is required in transparency painting. It is sold at a very cheap rate.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1400. VOL. XXXIV.—MARCH 4, 1887.

FIXING CRAYON PRINTS.

WHEN photographs are finished by crayons or chalk they are very liable to become damaged or destroyed by the slightest abrasion from contact with any other print with which they may be placed in contact, or even by the paper which has been placed over them by way of protection.

Now that the production of enlargements is carried on to a greater extent than formerly, photographers may not only be held excused, but are to be commended, for striving to improve their work, or at any rate to remove any imperfections by the judicious application of chalk or crayons. It is surprising what improvements may be effected by a few minutes' work with a charcoal pencil, a crayon stump, and a nicely pointed ink eraser.

It does not require a very high degree of skill, provided one is imbued with taste, to apply not only black chalks but also coloured crayons to an enlargement, if one does not at first aim too highly. We know, however, from the correspondence we receive on the subject, that many of our readers are possessed of artistic skill quite sufficient to prevent them from making any serious mistake as regards the art aspect of the matter.

Crayons or pastels are so easily procurable at such very moderate prices, that we would recommend a complete set of the different colours being kept by all who do enlarging, either as amateurs or professionals. The bases of the better sort are formed, *inter alia*, of finely ground chalk, pipeclay, plaster of Paris, oxide of bismuth, kaolin, and magnesia, and the colours are composed of an almost infinite variety of earths and metallic salts, such as those of copper, iron, cobalt, and others.

Photographs taken with a special view to being finished in crayons should not be on albumenised paper, but on a surface on which there is a tooth. The paper now employed for enlarging by the bromide process lends itself admirably to being worked on by crayons, and no preparation is required to make the pigments bite. This, at any rate, is our experience. It would be rather out of place here to describe the various methods that may be resorted to in order to blend one colour with another by the agency of the leather or paper stump, which stumps are articles of commerce, but we may observe that it must be done with judgment, in order that the tints be not rendered flat or opaque.

But assuming that the picture has been finished, we now come to the practical inquiry as to how the pigments, whether black or polychrome, are to be fixed.

There are numerous varnishes or solutions which, if flowed over the surface, would undoubtedly fix the pigments, but

would make them flow into each other, producing a veritable smudge and cause the picture to lose all its effect. What has to be aimed at is the application of some means by which each individual touch will retain its identity without, so to speak, obtruding itself on the domains of its neighbour.

This is best done by laying the finished print face down and sponging its back with a fixing liquid prepared by the following means:—Place in five ounces of rather weak acetic acid an ounce and a half of gelatine, and, after allowing a few minutes to soak, add a quart of hot water. Place this on the hob and allow to remain there until perfect solution of the gelatine has taken place, which will soon be effected by occasional stirring. When it has become cold it will be sufficiently fluid to admit of being filtered, which may be done through a piece of cambric, and then add an equal bulk of spirits of wine. After shaking well up the solution is complete.

This when applied to the back of the print speedily penetrates the paper, and entangles, so to speak, the atoms composing the pigment. This is rendered apparent by the colours acquiring a peculiar moist shining appearance. The picture is now allowed to dry, when the crayons will be found to be perfectly fixed. As there may be a slight lowering of some of the pigments it may be necessary to go over the picture again when dry, merely touching a point here or there.

The method above described is one which is adopted by most artists, but some prefer fixing their colours by immersing the prints in water saturated with alum, in which has been dissolved gelatine or isinglass in the proportion of an ounce of the gelatine to a pint of water, to which is afterwards added six times its bulk of spirits of wine. Methylated spirits answer quite well. This solution should be made slightly warm previous to immersing the prints.

Another solution used by artists consists in dissolving half an ounce of gelatine in three pints of water, and after being heated to the boiling point, dissolving therein half an ounce of white soap. Allow to boil for fifteen minutes and then add a quarter of an ounce of powdered alum. When nearly cold filter through muslin, and when quite cold add half a pint of spirits of wine.

ON BUSINESS MATTERS.

How is it that so many old-established portrait photographers, at the present time, are complaining of the lack of business, while others, comparatively newly established, are apparently in a flourishing condition? A commercial man remarked to us the other day that profitable portrait businesses appeared to be

divided into two classes—the very high priced and the very low priced. Those establishments with medium prices—say, ten shillings per dozen for *cartes*, for example—were, he said, those which are now suffering most from depression of trade.

Many of those who are now lamenting over the exceedingly low prices they now obtain for their productions have in many instances, we venture to say, only themselves to blame. Here is a case in point that will serve to illustrate several others which have come under our observation. In a medium-size provincial town was a well-established photographer, whom we shall designate Mr. A. His establishment was situated in the principal street. He produced excellent work, obtained high prices, and had the leading business in the town and surrounding district, which, by the way, included a large number of the nobility. There were other photographers in the town, but they were in minor streets, their prices were low, and their work inferior. Hence Mr. A. had the whole of the better class of business in his hands, without opposition, for many years. Eventually another artist, of not less ability, opened a studio in the same street, and fitted up his establishment somewhat expensively and with great taste. He also exhibited pictures of a larger size, and of a more artistic character, than had hitherto been produced in the neighbourhood. His prices were fixed but a trifle below those of Mr. A. By business tact, coupled with the production of work in keeping with the appearance of his place, he soon secured a good trade, although, photographically, his work was in no way superior to the other man's. Mr. A., on finding his trade being transferred to the new comer, came to the conclusion that the slightly lower prices were the cause, and forthwith, most unwisely, reduced his charges to considerably below those of his competitor.

That the reason for the loss of trade was not due to the lower price was easy to see by a visit to the two establishments. In the new one everything was bright and fresh and in good taste. The furniture and fittings of the reception and dressing rooms were of the most modern type. The specimens were all recently taken, the sitters being attired in the latest fashion of the period. The studio and its appointments were in keeping with the rest of the premises, everything being clean and tidy, whereas, in the old establishment, all the furniture was conspicuously the worse for wear, and the carpets were faded and partly threadbare. In the studio the backgrounds and accessories were the same that had done duty for many years and were quite out of date, while the curtains, like the carpet, had become faded and dirty-looking. In a word, the whole place had a dingy and forlorn appearance. Under these conditions it was not surprising that the reduction in the prices made no material improvement in the trade, as the original high-class business was never recovered. This particular business has changed hands several times and fresh photographers have set up in the town, yet Mr. B. is the leading man and still maintains his original prices. But, it must be mentioned, he is continually renewing his specimens as they become out of date, changing his backgrounds and accessories as well as replacing everything as it becomes shabby.

On mentioning this particular instance to a commercial traveller for one of the large wholesale houses, he assured us that, within his experience, he could cite scores of cases where old businesses had been lost and prices ruined in a similar manner, adding that it is a very common thing, when a photographer finds his trade going to another, to reduce his prices, instead of endeavouring to improve the character of his work or modernising his establishment so as to keep pace with the

times. When one photographer reduces his prices, others too often follow suit, and this leads to still further reductions, which ends in the ruinously low price, for really good work, so frequently met with in many country towns.

What has been said with reference to photography in provincial towns applies equally as well to the Metropolis. We have in our mind many old-established studios in London where the same thing has prevailed, and good businesses have been lost, and prices brought down, through lack of business tact and not advancing with the times. There is, we think, no question that in those establishments where the highest prices are obtained that the public are induced to pay them, in a great measure, through the appearance of the place itself. The reception and retiring rooms of these establishments are elegantly furnished, the appointments being of the most expensive character, while the specimens exhibited are always of modern production, so that the latest fashion in costume is secured, and this is an important point with lady sitters. The studios are also in keeping with the rest of the place, being furnished with accessories and backgrounds of the highest artistic order and most modern type. The whole place, in fact, by its appearance, inspires confidence that orders will be executed in keeping with the surroundings.

In some West-end houses we could mention, with old and well-known names attached to them, we find just the reverse. The carpets of the rooms are threadbare, the curtains faded, and the furniture devoid of polish. The coloured and finished specimens are the same that were there a dozen years or more ago, and are, of course, in all manner of old-fashioned costumes. There may be a few modern ones, but they appear to be lost amongst the larger number of ancient ones. The studios are, for the most part, crowded with accessories long since out of date and, consequently, quite unusable in modern pictures, while the blinds and draperies are either stained or faded. In fact, the place has a depressing effect upon sitters, and is apt to lead them to surmise that their portraits will partake of the antiquated appearance of the establishment generally. Consequently the extent of the orders given are often far more limited than they would have been in an establishment such as that to which we have previously alluded.

Much more might be written on this topic, but sufficient has been said to indicate why some businesses have declined while others are prosperous.

LAST week, when referring to negatives whose corners were cracked, we described an old laboratory expedient for leading a crack in any desired direction, a method which is often very useful for converting broken vessels of one kind into useful utensils of another description. Thus, we have seen a cracked "Winchester quart" cut into two, so that the lower part became a useful jar, while the upper, the neck part, was utilised as a funnel. It will sometimes be found in dividing glass in this way that the crack will decline to move, and the operation seem at a standstill; if, however, a drop of water be placed on the spot, or even it be touched with a finger moistened by the tongue, the consequent quick reduction of temperature will usually start the crack afresh.

THERE are occasions when it is wished to divide an uninjured glass vessel into two parts, and a very neat way of doing this has recently been published. Our readers are doubtless familiar with the older method by a piece of twine dipped in alcohol and set on fire after being tied round the selected spot, immediate affusion with cold water sufficing to cause the separation. Again, too, heating by the friction of a piece of cord kept in the desired place by two other wrappings of cord separated so as to form an annular space will, with cold water

again applied, cause the glass to crack at the required line of separation. Both of these plans, and many similar ones, are of very problematical utility in most cases; but the one we allude to seems to possess all the elements of practicability. As described in the *Chemical Society's Journal*, it runs: "A scratch is made with a file, at both sides of this pads of wet blotting-paper are wrapped round the object, leaving a space of a few millimetres between them. The flame of a Bunsen or gas blowpipe is applied to this space, when the crack will be carried round from the scratch midway between the two pads."

EVERY one knows how difficult it is to cause a label to adhere with any tenacity to metal; hence a reliable recipe for a paste or glue alike useful for metal, glass, or wood, will be useful to our readers. The following formula was given at a meeting of the American Pharmaceutical Association as being useful for the production of a paste answering all these requirements:—Gum tragacanth, one ounce; gum acacia, four ounces; water, one pint. Dissolve, strain, and add, Thymol, fourteen grains, suspended in glycerine, four ounces; finally add water to make two pints. Mr. Eliel, who gave this formula, says of the mixture, that "it will keep sweet indefinitely, the thymol preventing fermentation; it will separate on standing, but a single shake will mix it sufficiently for use."

In laboratories and dark rooms liable to fluctuations of temperature, one of the greatest annoyances connected with stock bottles is the liability of the labels to become loosened or detached through the continued action of moisture, deposited especially by a humid atmosphere following a cold day; so that, whenever a bottle with a label so loosened is, in the interests of cleanliness, subjected to an occasional polishing with the towel, it will often be found labelless. But all photographers have at hand every necessary for securing the label and adding to its appearance. It will quite suffice to brush over the label, when once attached, some of the usual mounting material of the establishment—be it paste, gum, or glue—and then, when it is thoroughly dry, to give the label a coat or two of photographic varnish, or a single coat of shellac cement if that be available. The label then is proof against everything likely to come into contact with it, and may, without injury, be washed under the tap as often as is necessary. It offers a striking contrast to the usual dirty grey of the label of an often-used stock bottle.

THE shellac cement above mentioned should be kept in every photographer's establishment, no matter of how modest dimensions. As a waterproof cement it is admirable, and will repair small objects with greater certainty than ordinary glue, while, when thin enough to serve as a varnish, it is invaluable for an immense variety of purposes—from dark slides and printing frames downwards.

This cement is by the experts usually considered to be best made by dissolving the shellac in wood naphtha rather than alcohol, but our own experience has been that one solvent was as good as the other, and, nowadays, methylated spirit may be far more easily purchased than wood naphtha.

At the Royal Society's meeting, on January 27, Mr. B. J. Burch described a singular arrangement of lenses for what he termed a "Perspective microscope" that he had devised. While endeavouring to devise means whereby the various planes of an object should be visible under the microscope without the adjustment of focus to each, he discovered that "when two lenses are separated by a distance equal to the sum of their focal lengths the optical conditions are such that the magnitude of the image bears a constant ratio to that of the object no matter where, upon the optic axis, it is situated—the ratio being the focal lengths of the two lenses; that a given displacement of the object causes a displacement of the image in the same direction, but in the square of the ratio. Further, that a picture drawn with the camera lucida under these conditions has the perspective of an object magnified in the square of the ratio when it is brought within the proper distance of the eye. The field of view of the perspective

microscope is small, but may be increased by using more than two lenses; but the writer believed that with glasses of wide angle, specially constructed, a high power with sufficiently large field might be obtained." The possibility of constructing an optical arrangement that should give the same size image no matter how far away the object was is too remarkable to pass without notice; we need not say, except for possible photo-micrographic work, it could have no real field of usefulness in photography.

BICHIROMATED GELATINE EMULSION PAPER.

It is a little over two years since I first described in these columns a method for making transparencies or reproducing negatives based upon the employment of gelatino-bromide or chloride paper, treated with potassium bichromate and used after the manner of carbon tissue. Little practical utility has, however, resulted from the process, in all probability because, as I pointed out at the time, the presence of ordinary or chrome alum in most of the commercial samples of paper caused them to become spontaneously insoluble after contact with the chromium salt.

I have personally frequently availed myself of the advantages of this method for special objects, preparing my own paper for the purpose, an operation, as I previously pointed out, much simpler and easier than is the case with glass plates, if only a suitable paper be obtained at the outset. Quite recently, however, I have met with a commercial sample of gelatino-chloride paper (Obernetter's) which answers admirably, all the requirements having a perfectly soluble layer of sensitive material of good body, and only requiring immersion in a two to five per cent. solution of potassium bichromate and subsequent drying to fit it for use. Here, then, is a chance for those who cannot or do not care to prepare this tissue or emulsion to try its value for the various purposes to which it is adapted.

So far from being merely an experimental curiosity as was suggested by one correspondent, or a "roundabout way of performing inferior work" as another was good enough to say, it produces better results in some departments than can be obtained in any other manner. Take, for instance, the reproduction of negatives, especially in such cases as necessitate some modification of the character of the original. Here there is of course the double operation of making first a transparency, and from that again the duplicate negative; and each operation of course affords the double facilities which the development of the bichromated gelatine film offers in the first place, and subsequently the reduction of the haloid retained in the insoluble image. Add to this that where extraordinary density is required, as for photo-mechanical processes, the doubly developed image is still further amenable to intensification both by staining the gelatine as well as by piling on more silver by the ordinary methods of silver intensification, it results that with a film very much thinner than one is accustomed to in ordinary carbon tissue, images of great force can be obtained, though where the utmost density is required, with a minimum of trouble, it is better to commence with a film possessing some substance.

For some descriptions of transparencies the process is often useful, and a very great variety of tones may be obtained of pleasing character to suit different subjects either on opal or plain glass, though this application does not offer the same practical utility as the preceding, since it is only possible to utilise it for contact printing from negatives of the same size as the desired positive. For lantern slides from specially taken negatives—that is from negatives which require no reduction—it gives very fine results, resembling Woodbury slides in transparency of the shadows, while the colour can be varied to almost any extent.

The toning of the metallic image according to the haloid employed and the method by which it may have been reduced, can be effected either by the ordinary gold or other substitution method, or by staining the gelatine film, which not only holds the image but is present in precisely the same varying thicknesses as the quantities of metal forming the different gradations. Thus a cold silver image may be rendered of a warmer and more pleasing tint by staining the gelatine red or purple, or a foxy red or brown may be modified by contrary treatment, or the bright red image produced by the long exposure and suitable development of a pure chloride film may be preferably toned with gold or platinum.

It must be borne in mind that the picture formed by the exposure and subsequent development in hot water consists of varying thicknesses of a mixture of gelatine and chloride or bromide of silver in the same proportions throughout, and that the highest lights, if the exposure and development have been correctly performed, consist of bare glass, carrying neither silver to reduce nor gelatine to stain. From which it follows, that however far the reducing process or the staining may be carried, there can be no degradation of those lights; that the only care necessary in the former is to see that it is carried far enough, and in the latter, or the toning, that the operation is arrested when the right colour is obtained.

For purposes of experiment I have treated the prints produced by this method after the manner of single transfer carbon prints; that is, I have transferred them after exposure to paper for the first development, but the result is not satisfactory, as the subsequent operations stain the support. But they may be developed on glass and finally retransferred to double transfer paper, when effects greatly resembling Alpha prints can be obtained if a chloride paper be used.

In using the Obernetter paper a full exposure should be given in the printing frame in order to get an image as rich in silver as the comparatively thin layer will permit; but I have occasionally experienced difficulty in stripping the original paper away in the hot water development, especially with "hard" negatives when the exposure has been prolonged. This I have attributed to the fact of the sensitive emulsion being spread upon paper prepared with an insoluble layer of gelatine, which if the whole thickness of emulsion be rendered insoluble by light adheres permanently to it and prevents the paper coming away.

The exposure will be generally much shorter than an ordinary carbon print, on account of the light colour of the sensitive layer, which permits the light to penetrate more rapidly and deeply. One other method I have tried with tolerable success places the paper more under the conditions of ordinary pigment tissue, and practically prevents the light penetrating to a sufficient depth to cement the image to the paper. This consists in exposing the emulsion paper to light before treating with bichromate in order to blacken it uniformly, and if possible throughout its whole thickness. It is then, when sensitised, practically bichromated tissue, pigmented with reduced silver of the same tint as that presented by an unfixed gelatino-chloride print produced in the ordinary manner, and when developed the image simply requires toning, without any fixing to complete it.

In employing the commercial paper I find it better to employ a rather weak bichromate bath, as this enables the comparatively thin film of emulsion to present a stronger contrast than would be the case if a sensitising solution of ordinary strength were employed. About two and a half per cent. I prefer, and I make the solution as follows. Take—

Bichromate of potash	$\frac{1}{2}$ ounce.
Ammonia.....	9 s.
Water	10 ounces.

Dissolve the bichromate and then add sufficient ammonia to remove the deep orange colour of the solution, taking care not to render it alkaline. Then add—

Chloride of sodium	1 drachm.
--------------------------	-----------

Dissolve, filter, and the solution when cold is ready for use.

The chloride of sodium is added with a view of converting the free silver in the paper; if this be not done, the paper when sensitised will be of a bright red colour from the formation of silver chromate, the effect of which in the subsequent operations, beyond lengthening the exposure, I am unable to speak to, not having tried. The paper is immersed, or floated face downwards on the solution until it lies perfectly flat, after which it is drawn over a glass rod to remove the superfluous solution from both sides, or, better still, squeezed on to glass for the same purpose and then hung up to dry, which it will do very rapidly. It should not be dried in a room where gas is kept burning for any length of time, and it is needless to say that the same precautions as would be taken with albumenised paper to protect it from light, or even greater, must be observed with this.

I omitted to say that the practice adopted by some carbon printers of sensitising by floating the back of the paper on the solution will not answer in this process, or at least with this particular sample of

paper, as the insoluble substratum causes the bichromate to penetrate imperfectly and unequally.

When perfectly dry, the paper is ready for the printing frame. In cutting it to size, it is advisable to use scissors or a sharp knife, in order to leave clean edges, which will greatly reduce the chance of the picture leaving the glass during development. It is also absolutely necessary, as in carbon printing, to employ a "safe edge," that is, a mask of opaque paper; or when the negative is to be printed full size, an edging of black varnish is applied to it, in order that a narrow strip round the edges of the tissue shall be protected from the action of light. If this be neglected, if indeed the smallest portion of the edge of the print be hardened by the action of light, it is certain to leave the glass during development. H. Y. E. COTESWORTH.

(To be continued.)

PHYSICAL PROPERTIES OF COAL-TAR COLOURS.

As a good deal of interest is now being displayed in the action of various dyes on gelatine dry plates, it is desirable that the conditions of the solution and application of these pigments should be thoroughly understood. I believe that dyes have an important future before them in connection with photography, not only as a means of making properly graduated negatives of coloured subjects, but also as a medium for producing coloured prints from those negatives.

If we try to dissolve the dyes, we find remarkable differences in their behaviour. Some, such as aniline blue, orange, and black, also most eosines, dissolve in cold water, but not in alcohol; others, as roseine, aurine, magenta, and crimson, dissolve readily in alcohol but not in cold water; while there are some which are only slightly soluble in either, such as certain yellow and brown pigments.

There is one solvent, however, which dissolves all these dyes, and that is boiling water. When the solution cools, the dye is precipitated as a fine powder; if it is a spirit-soluble specimen.

Some of the dyes, if dissolved in boiling water and then allowed to cool, are not precipitated, but remain in suspension in the liquid; they are still transparent, but usually have not the brilliance of tint they possess in the heated state. They are in the condition of ordinary artists' water colours, which do not form perfect solutions, for if left at rest for some time the colour settles to the bottom and leaves the liquid clear. The blue-green dye behaves in this manner in cold water, but is perfectly soluble in alcohol, in which it exhibits its full brilliance of tint. The eosines also do not always form a perfect solution in cold water, and if a gelatine plate is immersed in a cold solution of this, it will not really dye the plate, but will settle on the film in the same way as ordinary Prussian blue. The colour is thus applied in the form of a powder or paste, which however fine and impalpable in its composition, is not likely to have the same result that a true stain would produce. This is the reason why weak ammonia is sometimes employed in conjunction with dyes in order to effect a more complete solution, and thus obtain the effect that would be obtained by adding the colour to the emulsion at boiling water heat.

Hence we find that to produce a perfect stain or dye on a gelatine plate, or any other susceptible material, it is necessary to have a perfect solution, and not a mere holding in suspension of the dye in the fluid. If gelatine plates would stand dipping in boiling hot water, as a linen cloth might be treated, it would be a simple matter enough to dye plates properly; but as their constitution is not sufficiently hardy to stand such a procedure, it is necessary to adopt other means of staining, of which the ammonia method is one. The latter system, however, suffers from the drawback of requiring proper dark boxes for the plates to dry in, which usually takes a long time. If a suitable dye could be applied to an ordinary plate in the same manner and with the same ease as a film of collodion or varnish, and the gelatine was really dyed with the tint, I imagine the use of stained plates would become far more general than at present.

There are certain substances that are not capable of being dyed. Thus, for instance, I am not aware that gum arabic or gum tragacanth can be dyed. These gums may be dissolved in cold water and mixed with a solution of aniline blue, for example, but this results only in a mechanical mixture. The blue dye would also remain transparent when dry if no gum was mixed with it. If a solution of gum arabic is added to a magenta dye at boiling water heat and kept at that heat until dry, it will be found that the colour has become opaque, just as it would if no gum were present; in other words, no union has taken place between the two substances, and the gum is not dyed.

Now let us try gelatine in the same way; the result is totally

different. The gelatine dissolves in the hot water and combines with the dye, which may be any one of the coal-tar colours, and when again cool and dry, the gelatine will be dyed a brilliant tint, which cannot be washed out by cold water.

Hence gelatine is an excellent medium for applying dyes to the surface of glass plates so as to produce the effect of stained glass. The gelatine and the dye being first dissolved separately in hot water, and then mixed together while still hot, will form a mixture that can be spread on any surface as easily as undyed gelatine. It can be applied with a brush, if the plate and the mixture are both warm; and photographic lantern slides, or window transparencies, tinted with such colours, may be relied upon to be perfectly transparent, and as durable in their tints as the ordinary water colours used by artists. The dyed gelatine when thus used as painting material will far surpass the ordinary methods of colouring, both in richness of tint and absolute transparency.

Another way of preparing dyes, namely, with ox-gall and glycerine, as transparent colours, was lately published by me. This possesses the advantage of having "dabbing" capabilities, and also of being workable at ordinary temperatures; the tints so produced are not quite so brilliant in some cases, and being more liable to attract moisture, require protecting with mastic varnish, which is unnecessary with gelatine.

Plain collodion is an excellent vehicle for coating flat surfaces with dyes. These are first dissolved in a little alcohol, or in the case of eosine, aniline blue, and orange, in a few drops of water, and the solution added to the collodion. This tinted collodion may be used to coat glass plates, which will then be indistinguishable in appearance from stained glass. The collodion is really stained or dyed; the colour is so "fast" that neither cold nor hot, nor even boiling water, will remove the stain. Gelatine plates may be coated with such a film in the dark room; in this case, the gelatine is not itself stained, as the dye keeps to the collodion.

We may now turn to shellac as a medium for conveying a dye tint to a flat surface. It is much inferior to either gelatine or collodion for this purpose, as the colour loses all brilliance and becomes semi-opaque. For instance, if roseine is added to negative varnish, and a plate is coated with the mixture, the colour is at first a bright crimson, which rapidly turns darker as the alcohol evaporates, until it is of a dark violet tint, very different to the former. It is not easy to combine aniline, orange, and blue—which are insoluble in spirits—with a shellac solution, as the necessary addition of a little water causes a precipitate in the varnish.

Glycerine possesses the property of combining with most dyes, so as to hold them in solution without any precipitation of the pigment taking place. It is necessary to dissolve the dye in alcohol or water before adding it to the glycerine.

A solution of eosine and aniline blue or orange may be made in alcohol by previously dissolving the dye in a few drops of water and then adding it to the spirit. The solution in the case of eosine is then strongly fluorescent; and in the case of aniline orange, which is soluble in cold water, the alcoholic mixture is also fluorescent, though to a less extent than eosine. If fluorescence in dyes denotes any special fitness for preparing colour-sensitive plates, then aniline yellow or orange (the colour is between these two) is suitable for such a purpose. If such a dye is thus added to a mixture of water and spirits in the proportion of about one to six, a gelatine dry plate may be coated with the mixture by pouring, as with ordinary varnish, and will receive a uniform film, and if the plate, before coating, is heated to about 200° and then coated with the solution, the surplus portion of which is quickly poured off, the result will be that the alcohol will first evaporate, leaving a thin liquid film of the dye in water on the hot plate. This water is of course instantly absorbed by the gelatine, and the heated surface of the latter is at the same time dyed by the pigment. The quantity of water left on the plate is so small that the film is dry in a very short time and ready for use. To secure a perfectly uniform stain it is perhaps advisable to use a weak solution of the dye and to repeat the dyeing process two or three times, heating the plate between each application, and using a different corner each time to flow off the surplus fluid by.

A light-tight tin box may be used to enclose the plate during the heating, which can easily be done over a gas burner.

It seems to me that such a means of applying a dye insoluble in alcohol is equivalent to the use of weak ammonia with the colour, and the time necessary for the drying of the plate in the latter system is saved. The dye is mainly confined to the surface of the film, which should be an advantage, as tending to produce greater vigour and pluck in the negative. It is only in the high lights that the deposit of reduced silver reaches the back of the film; the half tones are confined to the surface.

ALBERT WM. SCOTT.

PORTABLE DARK TENTS.

"Why should spirit levels be loose?" was recently asked in the *JOURNAL*. Why, indeed. I lately saw a 15 x 12 camera made by the *dozen* of the craft for outdoor use in the Peninsula. The base-board had a couple of oblong levels let in thus——an arrangement, I should imagine, of immense service in plumbing the camera. The idea is, of course, far from novel, the single level in the base-board being, comparatively speaking, as old as the hills; nevertheless, I think it is of sufficient utility to deserve the notice of those sticklers who are constantly on the alert for time-saving fads. Levels suitable for the purpose being so cheap, the wonder is that they are not in greater use. Oddly enough, nearly every instructor and instruction-book vaguely counsels the tyro to "judge" when the camera is properly adjusted. This is simply scamping a highly important department of the procedure preliminary to exposure. "Judging" should be avoided when certainty of correctness may be ensured so easily and cheaply. *Appropos* of time-savers, it seems incomprehensible that to the so-called "Patent" cameras only two very excellent but simple methods of husbanding time and trouble should be applied and not to the ordinary or "garden" variety—costing, as they do, less to engineer than the older and less useful methods. I refer to the small stretches of grooving (I have seen a "catch" fixed for the same purpose, but catches on the camera are best tabooed) that permit of the double back being fitted to its place, without the necessity of sliding, and also to a similar idea applied to the lens front. True, these are old dodges; but the pity is that they are not more widely taken advantage of, for their value to-day is greater than ever it was. His dark back and front affixed to his camera in this manner, the peripatetic tourist laughs at warpings, swellings, dry and moist vagaries of mahogany, and the endless other "cussednesses" to which his erratic apparatus is ordinarily susceptible. Who has not endured the agony evoked by the double back that would not slide in the camera without ruining the focus of the picture, or the eccentricities of his sliding front when in a similar mood? which brings me to a suggestion concerning the use of alternative lenses.

I presume the difficulty experienced in rapidly substituting one lens for another has been felt by all landscapists at one time or another; but I hold that a "turntable" as a commercial success is an impossibility. It would be a very fine notion if everybody used exactly the same lenses as their neighbours—but they don't and won't. Now in modern view lenses the range of size is not very great. Remembering that the chief makers readily gave in their adhesion to the adoption of a common system of diaphragms, might not an attempt be made to induce them, in the instances, say, of their symmetrical and rectilinear series—which up to 12 x 10 are quite portable—to fit to them flanges of uniform diameter which would admit of instant union with the front flange, bayonet-joint fashion, or otherwise? This idea though necessarily crude, will not, I hope, be deemed altogether Utopian. Assuredly the present manner of fixing the lens to the camera front and the awkward fact that mostly a fresh lens demands a fresh front are miserable survivals worthy alone of limbo.

If, in the foregoing reflections I have rashly trodden ground which the accomplished apostle of the camera of the future has made all his own, I trust that this slight contribution to the literature of his ideal—an ideal, I'm afraid, some distance off realisation—will not be despised. Truly, remembering his '84 and subsequent advocacies, one is tempted to envy Mr. Harrison his perennial enthusiasm; although whilst applauding his devotion to a pet dogma one cannot help thinking that under his tutelage the camera of the future—like the music of that persecuted period—would be something fearful and wonderful to contemplate. Micrometrical adjustments, *et hoc*, are luxuries; luxuries are the quarry of epicures; and epicures were once defined by a mudlark as "Coves wot's allus eatin'!" But to my subject proper.

Probably in all the press and hurry of the many reforms engendered by the successful introduction of the popular negative process now in vogue, few of the implements without which at one time no photographic kit could be considered complete have undergone less alteration than the portable dark tent. Once upon a time the amateur tourist was a veritable *rara avis*; only professional landscapists systematically stumped the country, a dark tent in some shape or form, and very often on wheels, being an indispensable item of their baggage. This demand led to the introduction of the dark tent as at present known to us; in reality it is lineally descended from the poor and battered movables one sometimes encounters at Hampstead and elsewhere. Dark tents and dry plates, somehow or another, seem to have little affinity. About the former I cannot help thinking there still lingers an indescribable collodionic aroma. They belong to other days; they come of a period which wanted levelling up to the exalted sensitiveness boasted by modern films, when lightness and compactness of form were not *desiderata*, when space was less valuable, and ten pounds in weight of

less account than as many ounces are now. The four or five varieties of the tent now in commerce bear a strong family likeness to each other, and to their ancestors who dwelt among us a score of years since. Dry films, which have revolutionised the camera and many other things, such as lamps and stands, seem to have had no chastening effect upon these obstinate old tents, which fact should be noted down as a curiosity in its way. Why is it? I wonder that the inventor's brain, which has been so busy in many other and far less important paths, has entirely ignored the poor dark tent, which, if a necessity of photographic practice twenty years ago, is equally, if not more, an object of paramount importance under existing conditions. This is surely a point deserving of our attention, for there is most certainly a field open to some of our inventors if they will condescend to transfer their prolific ideas from the arid deserts in which they are at present roaming to the more fertile plains indicated.

A portable piece of apparatus, call it a tent or what you will, that may be carried about from place to place with the same ease as a camera, and in which any number of plates may be developed, is essential to the practice of modern photography. Development in the field and away from home has no more been obviated by dry films than a plurality of slides has been rendered unnecessary by the introduction of a paper support. Development just after exposure would be vastly more popular if the means were at hand; the reason that there is such a wide predilection in favour of postponing development until one's return from the country or abroad, is that no serious attempt has been made to provide tourists with an efficacious developing media—for the portable dark tent certainly is not. Few country houses and fewer hotels possess or are likely to possess dark rooms—a recent attempt to induce hotel proprietors in this country to attach them to their premises having proved abortive, as it was bound to—whilst the studio of the local photographer is only available in the minority of cases. Tentative development, *en route*, is a great boon, but it is rarely possible, especially on board ship, or in foreign hotels and strange places generally. Hence, there is ample scope for the introduction of a really good developing tent. The inference that the present tent of commerce is not a good one will be readily drawn, and it therefore behoves me to endeavour to account for its comparative unpopularity, and its paucity of numbers amongst outdoor workers. I can do so in a couple of sentences. This so-called dark tent is not portable at all. It is cumbersome, unmanageable, and generally archaic; it is twice as heavy as it should be; it is not ventilated; it is too dear—in fact, this same dark tent was built for wet-plate work, and dry-plate workers have a right to demand a new edition of it brought down to date. Let us hope it is in the press. To resume: A whole-plate tent and stand weigh (without case) something like twenty-seven pounds; a 10×8, thirty pounds; a 12×10, thirty-three pounds. The whole-plate is useless; it is too small—one literally has not room to move properly. The 10×8 and 12×10 admit of the elbows being placed at an akimbo angle, but their several weights (the tents, not the elbows) are appalling.

MARSTON MOORE.

(To be continued.)

THE OFF SEASON.

WINTER! the very name has a depressing influence on photographers, and its actualities—widespread trouble and inconvenience. Fortunately, as years pass on, new processes are discovered—films so sensitive to light that the dull and dreary period is robbed of half its horrors; in another decade ordinary studio work may preferably be done by gaslight, who can say? Formerly, with the dark weather came enforced idleness, sitters were few and far between, and negatives left a great deal to be desired. Icy cold was the usual temperature of solutions, bottles, plates, and fingers, and an hour or two each morning was devoted to a general warm up, with cracked bottles and glassware generally to be reckoned amongst the casualties of the week. With the landscape man the whole paraphernalia of his occupation was relegated to out-of-the-way shelves and corners, there to lie perdu until the longer days and brighter light of spring once again fanned the dormant spark of his enthusiasm and he was tempted to overhaul, repair, and put into working order all that might be required for a summer campaign.

The greatest winter trouble now is snow filling up and blocking out the little light there is. With the flat or wide-angle roof most trouble of all is experienced, both in breakage and blocking, and after a heavy fall of snow a long time is occupied in clearing it away. High-pitched roofs are superior in every way; a good heat in the studio will melt the underlying portion and permit the snow to slip off by its own weight, an advantage not to be lightly estimated in glass roof construction. Another matter in this connection is having

easy access to the outside of the roof for painting, repairs, &c. Many otherwise unexceptional glass rooms are deficient in this respect, and the worry and inconvenience caused thereby is considerable. In cleaning the glass from the yellow smoky deposit that obstructs so much valuable light, it is most readily done with a rubber moistened with methylated spirit; water will often fail to thoroughly remove it. The light in winter being so much weaker than at other periods of the year, it behoves us to get rid of all possible obstructions. The probability of under exposure from this reason is supplemented by lowness of temperature indicates the use of solutions artificially heated. There are few plates that will not stand a temperature of 65° to 70° without injury. Developers and fixing baths should not, therefore, be below this temperature, more especially the hyposulphite bath; the washing water also should not be less than 60°. The effect of low temperature upon different solutions has been recently and ably written upon in this JOURNAL, in which the author pointed out the variations of the strength of saturated solutions altering with the temperature, a very important fact, and should always be kept in mind.

It will be, therefore, seen that a variety of causes may operate at one and the same time to interfere with the production of the photographic image in cold, gloomy weather, that are altogether absent under more genial circumstances. Printing operations are also much interfered with; but the principal danger to be apprehended is imperfect fixation of the proof unless the matter of temperature is strictly observed, as a very cold solution of hypo is almost inert. Warm water should be used all through the toning, fixing, and washing operations; and if possible the whole of the workrooms should be properly and comfortably warmed. So much, then, for conditions of successful working, about which a little reiteration is not only allowable but necessary.

A great deal of the trouble of winter photography has been abolished since gelatino-bromide plates came into general favour. They are always ready for immediate use, and by their extra sensitiveness available for working in such light that was under the old dispensation useless; but I am inclined to think that neither rapidity of plates or time of exposure are equivalent to a good light, or make up for it in any way other than a sort of compromise. It is true if we can see an object we can photograph it, and, even in a very bad light, get detail, but compare such a photograph with one of the same thing taken in a good light and mark the difference; quality will be wanting, and a certain amount of flatness will prevail that is fatal to fine effect. I think it may be set down as a rule that no subject having different planes where light and shadow are necessary for effect can be rendered as well in a bad light as a good one, even if all the requisite detail is secured. The question may be asked, What is a bad light? and answered by saying light is bad when small in quantity, of a bad colour and wanting in transparency, and what there is of it falling in a wrong direction. Want of transparency in a bad light is its worst fault, and to this we may attribute its attending effect. The fact of it being small in quantity induces one to use as much of it as possible, and this again induces the danger of it falling in a wrong direction. So we may consider unless the object to be copied is on one plane, as a drawing, for instance, no exposure will obtain a result equivalent to one taken in a good light. Winter work of the best quality in the studio is limited in its scope when dependent on ordinary daylight. Artificial light may, however, supply its place for many purposes with advantage, especially in copying by contact, making lantern slides, photo-micrography, and reproducing negatives. The uniformity of such artificial light is so great an advantage that work of this description is preferably done by it both winter and summer.

Landscape photography in winter is practically a dead letter, with one exception, and that is for snow and frost effects, and, as if to make up for its deficiencies, these effects are exquisitely beautiful, more so than almost any other kind of picture, but, like anything else exceptionally desirable, the trouble in securing them is proportionately difficult. The physical difficulties of tramping for miles up to the knees in snow, weighted with camera and traps, is no mean one. Happy they who reside in the midst of their hunting-grounds without having a tiresome journey before they begin work. These are exceptionally fortunate, as the finest hoar-frost effects last so short a time that half an hour may be all the difference between success and disappointment. The few opportunities offered to residents in large towns prevents any great amount of practice in this direction, and there are no doubt thousands of photographers who have never attempted it.

The beautiful pictures that occasionally grace the walls of our exhibitions show the possibilities of winter work, and are, in fact, a revelation; and dry plates also make it comparatively easy. Precautions that will conduce to success are: Firstly, exposure, which must be somewhat short, say two seconds, as compared with three

without snow; secondly, plates that will work without blurring; and, thirdly, a developer that will give good contrast. One successful worker in this direction advocates the use of very weak and slow developers; but whatever method of working is adopted, the resulting negatives must not be very dense, and must be clear in the shadows. Over density produces a chalky effect, and in printing by the time any detail is obtained in the light portion that in the shadows is hopelessly buried. Thin negatives are therefore indicated. Snow is at its best directly it has fallen. It soon loses its light, feathery character, and by partially melting and settling down becomes more opaque and solid, and a photograph of it is more chalky in effect.

To the casual observer the snow seems lighter in tint than the sky; this is not the case, unless under special atmospheric conditions, such as a yellow cloud in front, and the sun at the side or back of the observer. Snow having no luminosity in itself can but reflect part of the light it receives, and so must necessarily be darker than the sky, from which the illumination is derived; in the majority of instances diffused light is all he has to work by. If, however, he is so fortunate as to get with good snow blue sky and bright sunshine, the more prominent surfaces of the snow will reflect light sufficiently strong to equal that of the sky on the photographic plate, and possibly with orthochromatic plates be rendered lighter than the sky, but in a general way, with ordinary plates, the sky will come out lighter than the snow. The great difference in the respective luminosity of sky and snow, to the advantage of the latter, as usually rendered in paintings, is artistic licence, and not according to nature. There is no denying the *impression* conveyed is more realistic, and being so, is quite justifiable.

General landscape work in winter is always unsatisfactory; there is a bare desolateness about such views that does away with much of their charm. The absence of ground foliage is one of the greatest drawbacks to picturesque effect; the edges of rivers and brooks are smooth and monotonous; in rocky scenery the vegetation, what there is of it, hangs limp and withered. It is by attempting such work that the great value of foliage in picture making is thoroughly appreciated. The seaside is perhaps little changed as anywhere, but the cold winds and general discomfort are serious checks to enthusiasm. Now and then a good picture or special effect—skating scene, for instance, may be secured; but, take it all together, general landscape work in winter is better left alone, the game is scarcely worth the candle.

Snow scenes made up in the studio are more popular in Canada than England, and many very excellent imitations are turned out. Owing to the dryness of the atmosphere, salt is a favourite means of representing fallen snow on the ground and surroundings, but would in this country be unsuitable. I have found coarse oatmeal answer very well and give a good snowy effect on draperies and easily shaken off afterwards. The effect of falling and drifting snow is obtained by sprinkling the surface of the negative with Chinese white made into a suitable consistency with water and distributed by aid of a tooth-brush charged with it drawn across a comb, or a spray diffusion may be used. To give the effect of drifting, a soft camel's-hair brush is drawn lightly across *from the lower to the upper part* before the white has dried; this, on the information of Mr. Edwards, is the method adopted by Notman, of Montreal, a gentleman whose work in this direction is well known. In addition to this a few flakes may be specially painted in with a brush, and others also removed from the face where they interfere with the effect or injure the likeness. Bad weather of the off season may be utilised for experiments and repairs, and to a photographer of an ingenious turn of mind affords a leisure to work out pet ideas that in the bright summer weather may be put to the test of utility.

EDWARD DUNMORE.

PORTRAITURE.

[A Communication to the Camera Club.]

THE most difficult branch of photography is portraiture; and not only is it the most difficult to learn, but it is also the most difficult to treat well in words, for the correct delineation of the human form being the highest branch in all the arts, it therefore requires the most skill.

If the beginner have not already a knowledge of the art, nor an acquaintance, somewhat familiar, with the works of painters of note, he will find his own work the easier—it is needless to say better—by studying the celebrated figure-pieces and portraits in the National and other galleries, especially those of the Old Masters, Sir Joshua Reynolds and Thomas Gainsborough. Among the first, Murillo's *Spanish Boy* may be studied for the lighting of a face almost wholly

in half tone, and the management of the high light on the shoulder and cheek. The child in the same painter's *Holy Family* is a beautiful example of the action of a figure; the lighting in it may also be noticed for the method with which all the surroundings are made to tend to the principal figure. Van Ostade's *Portrait of a Boy* is another picture full of lessons in portraiture. Of the two latter masters, *Portraits of Two Gentlemen*, by Sir Joshua, teaches the arrangement of two figures in the one picture, neither attracting more attention than the other, at the same time it being complete as a whole. *Portrait of Himself*, by the same, should be observed for the high light. In Gainsborough's *Parish Clerk*, the carrying on of the light to the hand and top of the book show the value of balance in light and shade, while the shadows of the face should be specially noted. For the management of background in reference to figure, George Romney's *Parson's Daughter* can teach us much, by observing that it is darkest at the base of the picture, becoming lighter towards the centre, and darker again at the top, thus giving the feeling of atmosphere. Sir John Opie's picture, *Mary Wolstoncraft*, is a fine lesson in the turn of a head. And lastly, for figures and landscape combined, *The Vagrants*, by Walker, should not be overlooked, as this picture in itself may be said to teach everything. In the landscape the light and shade and lines all tend to the highest light in the distance, while in the figures, the movement and repose, grouping, and the effects of outdoor lighting on the faces, should be observed; while, finally, lines of drapery may be learnt and understood in the standing woman's figure. Also, it should not be omitted to notice the yellow tints of the farthest middle distance placed immediately against the distant blue, that makes the spectator feel the stretch of country lying between, though out of sight—photography may be made to render this effect quite correctly, as blue, the colour for distance, photographs light; while yellow, according to its admixture with other colours, is rendered darker.

These are only a very few of the works that may be studied; but, to the writer's mind, they are those most full of teaching, and are specified in the hope that what has been said will guide the beginner to what he ought to study, and to what he should see in each. He will find by close observation how nearly allied in their work are the colours themselves and the shades that represent them; but to render them truthfully in a photograph great skill is required in the knowledge of their work and action on the silver salts.

In looking at all good portraits, it will be observed that everything is made subservient to the figure; not only that, but tending to it; and in the figure itself all the lights are subordinate to the light on the face, which is the principal object. Hence in the studio the background should be selected very carefully. It is a good plan, if the room be given entirely to work of this and kindred natures, to have the walls papered with some patternless paper of a light-reflecting colour; pale blue-grey is about the best, as it will reflect sufficiently to brighten the side of the figure away from the centre of light; at the same time it will not give a white result with long exposures. Others of different tints, or partly shaded, may be used, being kept rolled tight to prevent creases when not in use; but these can be dispensed with if the photographer learn to shade the permanent one by using screens in various positions, causing them to throw soft shadows, that will darken it in the proper place without intercepting any of the rays falling on the figure from the centre of light—which should have curtains of some gauzy material for drawing over when necessary.

Now, to make a good portrait—by that I do not mean merely a representation of the sitter's features, but a picture representing individuality—many things are necessary which must be carefully observed and thought about. This can best be explained by reference to the illustrations, practice afterwards giving rapidity to the process.

[The paper here referred to an interesting series of examples sent by Mostyn Clarke as illustrations of the points he wished to emphasise, and concluded as follows]:—

Before proceeding to the question of exposures, a few words may be said on the subject of the proportions of the boundary-lines of pictures, which are, in some cases, the actual frame. It will be enough to suggest the two following facts, resulting from observation, leaving you to reason and apply them for yourselves.

The length and breadth of the frame must be relatively proportionate to the length and breadth of the figure shown.

The distance between the top of the frame and the highest point of the head will be found to decrease, and that between the side of the frame and face (on the outlook side) to increase proportionately as the length of the frame increases over the breadth, and *vice versa*.

By the word "frame" in the above is meant the boundary-line of the picture itself, and not the outer frame.

The exposures necessary for portraits taken in a studio such as that described cannot be otherwise than protracted; therefore it is well to choose such positions as will be the least trying to the sitter's powers of remaining at rest.

The reason, as before stated, for this great length of exposure is, that without it we should have no broad sweeps of light and shade, but rather patchy results. For the exposures of portraits out of doors a shorter time is required; about five to ten seconds, according to the state of the light and the time of day, the light being strongest from about eleven until two o'clock, and considerably weaker after three o'clock in summer. A good idea of its varying strength can be obtained by the beginner experimenting with sensitised paper at various hours. As to the stops to be used for portraits in the studio, a medium ($\frac{1}{4}$ or $\frac{1}{8}$) has been found to give the most satisfactory results, as this size does not protract the exposure, while it keeps the high lights under control. For outdoor portraits the rules are the same as those for landscape.

J. F. MOSTYN CLARKE.

THE LANTERN ARRANGEMENTS FOR MR. PRINGLE'S DUNDEE LECTURE.

MR. A. PRINGLE delivered a lecture in Dundee on February 10 before an audience numbering 2000 persons assembled in our largest public hall, and as the arrangements were on a scale a little out of the usual, and for the guidance of others placed in a similar position, I have thought that a few notes in the JOURNAL might not be out of place.

The arrangements were carried out by a small local committee appointed by the Dundee and East of Scotland Photographic Association, in consultation with Mr. Pringle. As the result of a former experience, it was admitted by most of the members present that a fifteen-foot, or even a twenty-foot screen, was simply nowhere in the hall to be used by Mr. Pringle, which measured one hundred and twenty feet from wall to wall. A screen which in a smaller hall was quite large appeared in this hall like an illuminated saucer. It was simply swamped by the great space around. It was decided to make a sheet of the proper size for the hall, that is to say, of such a size that when looked at from two-thirds of the hall's length back the picture would appear of natural proportion. After some "big thinks," thirty feet was decided on as the size of the sheet, which was manufactured of a good cotton, six feet wide, the seams running the whole length of the sheet in one direction. Brass rings about one inch diameter were securely fastened at one yard apart all round.

The next question was the illumination of this immense stretch of sheet. An ordinary blow-through jet was of course useless, and a mixed jet almost as bad. There was in contemplation the manufacture of a compound jet to play on a lime cylinder two to three inches in diameter, but after a further "big think" it was cast aside and the electric light thought of, notwithstanding the division of opinion lately expressed with reference to the electric light at the South London Society's rooms. This decision of the Committee leaked out, and amongst the other members there was a good deal of head wagging and "Take care! beware!" sort of thing. "Mr. Pringle must not be made a fool of, you know," said one. "If you use that blue, spluttering, fizzing abomination, we will have a regular *fiasco*," said a second. While a third suggested that in any case a limelight lantern should be held in readiness.

The question of *lime versus electric* light was settled in the minds of the Committee somewhat in the following way:—To illuminate this sheet properly by limelight, whatever the actual arrangement employed, would require from twenty to twenty-five feet of oxygen per hour at least, and this quantity, if burnt in the particular lantern proposed to be used (one having four-inch condensers) would mean so much heat at the condensers as to make it highly injudicious to risk it, or, as we say in our local vernacular, it would be "fell risky." A six or eight-inch condenser might have been substituted for the four-inch, but after all, and "taking one consideration with another," the limelight presented considerable although, perhaps, by no means insurmountable difficulties.

On the other hand, when it was considered that two members of the Association were practical electricians, that our ex-President offered a dynamo, and that the hall was advantageously situated as regards power, it will be seen that there was strong inducement to use the "blue and spluttering" illuminant. On putting the two electricians under oath, and duly impressing them with a sense of the great responsibility resting on the Committee, it was given as their unprejudiced opinion that were the electric light properly manipulated it would neither fizzle or splutter, or be in the least blue. The Committee cast the die on the side of electricity. What was the result?

On a night of rehearsal previous to lecture, when the whole apparatus was tried, the disc appeared not so bright as might have been expected, and the light hissed and roared in a most ominous manner. Moreover, something went wrong with the dynamo, and altogether things were not quite so satisfactory as might be wished. But the electricians said that everything would be right in their department, and if everything else was right there would be no failure. It was at once decided to wash the screen over with sized Paris white to increase the light on the disc, and

this was done in the following manner:—The rings along the top of the sheet were hung on nails driven into the bar which was to support the sheet on the night of lecture. This bar was capable of being drawn up a little at a time by block and tackle. Three men, each with a pail of the wash and an ordinary flat brush with short handle, set to work and finished in two and a quarter hours, drawing up the sheet as they finished a length horizontally. The washing was begun at eleven p.m., at a time when the hall was very warm after a crowded concert, and next morning at eleven it was not yet quite dry, but very nearly so. Let it be noted that to have the highest effect whitewash must be quite dry. As a guide to others in similar matters, a period of fifteen hours after the work is finished is not too much to allow for the drying of a sheet of this size, and providing a safe margin. When the sheet was dry the surface was all that could be desired—a dead white and very opaque. The sheet was guyed, stretched tight, and draped with an ample supply of red cloth, presented to the Association by our ex-President. The lens employed was a portrait objective of nine-inch focus, which gave crisp definition to the edge.

The arrangements were completed by the formation of a lantern room, through a hole in the wall of which the nose of the lens projected, the fitting up of an electric bell between the lecturer's table and the lantern room, and the adjustment of an instantaneous slide-shifting apparatus. I may be allowed to remark, as a piece of advice, that unless the electric current is to be obtained from a permanent installation, the greatest care should be taken that everything in connection with the machinery department be as perfect as possible. The dynamo should be very firmly fixed, and the driving belt should be an old one, or at least one that has been very perfectly stretched. The bearings of the machine should be provided with continuous lubricators, and the brushes carefully adjusted. Inattention to any one of the smallest of such details is quite enough to bring an exhibition to a premature end, but with ordinary and patient care there is almost a perfect certainty of success. On the night of the lecture everything, down to the smallest particular, wrought very well. The light was very steady and very silent, so much so that in the lantern room a whisper spoken by one of the operators was distinctly heard.

And now a word as to the employment of the electric light for optical lantern purposes. Objection has been taken to the colour of the light, if I mistake not, by Mr. Smith and others. On the face of it, this appears to me to be very absurd. When daylight is admitted to be "blue," and not of the correct colour for viewing objects and pictures, then the electric light may run some chance of condemnation, but as long as daylight forms the natural standard, the electric, as being perhaps nearest it of all artificial lights, cannot in the nature of things be held to give an unnatural tint. The tint may be unusual and quite different from an oil lantern—that is another matter. The absolute brightness of the disc is a matter of size of disc. The South London Society's disc, I understand, was eighteen feet. This may have caused too much glare; in other words, a picture too bright to be comfortably looked at, although I hardly think this could have been the case. Our Dundee disc, if the above figure be correct, was two and three-quarter times the London one in superficial area, and we can say that for the illumination of such a disc the electric light, in the opinion of every one present competent to judge, is everything that could be desired.

These few remarks are confined to the actual lantern arrangements. It would be most ungracious were I not to add that Mr. Pringle's lecture was very highly appreciated by the Photographic Association and by the people of Dundee, and that he has left an impression which will not easily be effaced.

G. D. MACDONALD

ON THE COMPOSITION OF THE PICTORIAL.

[Abstract of an Address given at the Photographic Club.]

The composition of that which is calculated to be made pictorial depends very much on the taste, aptitude, and culture, of the mind who desires to pursue it. It takes much time and application to those who are well read on the subject of art to put this into practice, for without a fine sense naturally of that which is picturesque there arises much difficulty in the selection of subject. However, when that is present it is gratifying to state that with a knowledge of leading principles, and the methods of employing them, the difficulties very soon disappear. The photographer has many advantages over the draughtsman, because when once he knows the proper standpoint to view the subject, nature, reflected by the camera, greatly assists him in the arrangement, whereas the draughtsman has to gather it all by his own mind and put it up besides. Certainly he has advantages again over the photographer that he can reject at his pleasure that which does not suit his arrangement, but, on the whole, it is much easier to compose by the assistance of the camera than it is without it. Never forget that the first essential is a feeling after the picturesque and what is really beautiful in nature, then comes the desirability of the art, by which one is able to select, separate, arrange, and present, that which is most valuable, beautiful, and impressive. It is to a knowledge of this, then, that I ask your especial attention to-night.

Two years ago I spoke on this subject at the South London Photographic Society. I had not then many prepared illustrations, neither

were they exhibited by the aid of the lantern, but since then I have prepared some lantern slides, and hope, through them, to show you what is to be aimed at and what to avoid.

The great properties of a subject in its treatment are balance of interest, but not equal in importance—being diverse in character, but always in unity—the principal part, such as a head, taking the lead, and the rest of subject matter following in expressiveness, in strict relation to each other, no portion unoccupied, and yet no redundancy. The more variety one can render in the treatment the more does it bespeak his knowledge and inventive power.

The importance of the limit or bounds of the subject, called the boundary lines, I now call your attention to.

Why is it that pictures are not constructed with the breadth and length of them being equal? My reply to the question is, You never see a picture in any exhibition so bounded, unless it be when a circular form is enclosed. Such pictures are unavoidably too much concentrated, consequently limiting diversity of arrangement; and the reason why lantern slides are so constructed is, because they serve the purpose of diagrams generally employed in scientific illustrations. But a diagram is not a picture, although, unfortunately, the square form of the ordinary lantern slide has been used in the exhibition of scenery, yet the subject should only have the boundary line suited to it visible; without this special limit to the subject it has not its peculiar attribute that defines the picture. This, I trust, will be fully demonstrated in the slides to be exhibited to-night.

[Here followed the projection of fifty-eight pictures on the screen, each of which was accompanied by critical remarks, which would not be understood without the illustrations. The first seven or so were diagrams illustrating the principle and method of pictorial boundaries—that the most perfect form of a parallelogram was made by the length being determined by the diagonal of the square of the breadth; that other forms might be used, but that the square shape of a picture was to be, if possible, avoided. That a parallelogram, when divided by odd numbers—three, five, or seven, each way—the intersections gave *forte* points, on which the principal parts of a subject were to rest; that they were to be varied in their choice, thus producing variety of treatment. Mr. Macbeth pointed out the importance of the place of the horizontal line, according to the subject—whether in a portrait, a landscape, or sea view. These, and a few minor essentials, were examined and explained in the varied forms of composition submitted by the illustrations, under different subdivisions, and always made by odd numbers, after which Mr. Macbeth continued.]

In bringing this lecture to a close, I trust that the principle of subdividing a given sphere constituting *forte* points, as now fully illustrated, is thoroughly understood, and will be found serviceable in the composition of the pictorial. Some have strong views in favour of naturalistic production only being attempted—i.e., taking nature simply as you may find it. They are very jealous of rules of art, regarding them as the conventionalities of schools. Well, if anything does give a true rendering or reflection of nature as it is at the moment, it is photography. But as you see every day in the attempts of beginners, there is little concentration of the subject, and no variety of treatment to make it interesting, consequently you must have recourse to some method in order to govern and regulate the subject, otherwise it stands a bad chance of being a picture. Imagine any one sitting down to a piano and rattling over the keys at any rate—what kind of music is that? As in the art of speaking or writing a language, a grammar must be introduced in order to regulate words and sentences.

It is a difficult thing to subject the rules of picture making to the requirements and capacity of photography. It is a branch of study meeting the claims of science as much, and fully more so, than that of art. To embrace the latter, the claims of art require much care and scrupulousness in what is introduced for its treatment. The tendency of photography in making application of art (especially the canons of fine art) is, that it attempts too much beyond its province and power. It is mainly a mechanical art, and very dependent on the instrumentalities and means for carrying out its designs—means and appliances not common to any other art—so that thereby its simplicity and purity is greatly endangered through the attempts of many who find the development of a plate otherwise easy.

In my former lecture I alluded to the attempts of building up a composition from various pieces of other negatives than that on hand, and which may have been taken for the very purpose. I hold that it is hardly legitimate to do so, inasmuch as the method is not only not so satisfactory as those otherwise gone about by the arrangements of actual objects made in the studio, with figures and accessories so placed so that you can ultimately photograph the whole subject in a completed state, but to have recourse to such a bolstered method with separate pieces, I think, is very unworthy of being allied to the higher associations of fine art. It has been asked, If artists do so why may not photographers? I presume when it is said that artists do so, it is meant they make studies from nature and apply them to a subject? Certainly they do, and without this application it is not to be expected they can do much if left to their own resources. Neither can the photographer. I wish him to make as many studies as he possibly can, try them in every advantageous way, then, when thoroughly conceived and designed, work out the subject on an actual field, either within or out-of-doors, and then

photograph the same in its completed form. This is, I conceive, the legitimate province of photography, and it should be carefully conserved.

Mark you, gentlemen, I do not object to any contrivance on that field, provided it is worthy of the subject, for nothing that is vulgar or mean in character should be tolerated for a moment. It is the exercise of a fine taste, as well as fine arrangement, that will elevate and ennoble such efforts. No one who knows the deep interest I have all along taken in the history and practice of photography, and especially in fostering and protecting the art element in association with it, must feel that I can have no antagonism to what I conceive to be a legitimate pursuit of it; but as to the method that is often resorted to in working out a composition by separate composite parts, I have very strong convictions against it. Very few who have attempted it have succeeded in concealing their contrivances, and have forgotten the old saying, '*Ars celare artem.*' The main tendency of such a method is, that the terminations of each part do not sufficiently blend with the parts in juxtaposition, consequently they appear not unlike the side-wings of a theatrical stage. I cannot understand why the simpler method to which I have alluded should not be attempted more. Perhaps it is for the want of accommodation, as such work would require a room for itself. Those who have outdoor accommodation would succeed admirably, and would well repay them for their pains, working out simple studies under the effects of natural light, either in direct sunlight or diffused. I am satisfied in my own mind that by this means you would successfully cope with the arrangements of higher art, provided you are able to control and regulate the action of your figures. The main dependence you have, after your own knowledge, is the feeling that you are able to infuse into your characters in carrying out your designs. It is in this that the merit of both Mr. Robinson and Mr. Diston's work mainly consists—not in their manipulative arrangements on a negative, for these are not unfrequently too apparent. I think it is Mr. Wall who has written in the *JOURNAL* concerning this (the feeling thrown in or rendered by the actors). If photographers would cultivate that more, they would immensely raise the status of their profession in the art direction, and lay claim to be next to the draughtsman in their ability to compose.

I have never yet seen, nor read of, any distinct definition or limit of the province of photography in relation to its application of artistic work, which it professes to take up. So far as I can make out, from what I see in its operation, it lies between the art of painting or drawing and dramatic or stage art. The former is called a fine or creative art, because of its influence to be entirely at the disposal of the artist, entering upon the treatment of his subject by choosing and rejecting at his pleasure that which is most suited to his necessities and wants, entering also into such niceties of feeling, subtle and delicate, especially in manipulation of drawing and colour. Some of these arrangements (as I have shown to-night) may be done by the photographer, but his power is comparatively limited, owing to his dependence on the lens (which draws for him). What he must do is the exercise of his judgment of the standpoint of the camera, construct his arrangement of subject, and develop. This is a great deal, but beyond that he is walled in. It is not his province to paint, neither on the negative nor on the print (excepting for defects purely incidental); the moment he does so he leaves his domain, converts his work into a mongrel, and renders his special art impure. It was certainly a retrograde movement when photography had recourse to the brush and other instruments (to meet the wishes of a vain and ignorant public), by touching up and remodelling the human face, destroying much that is valuable in likeness and character, making the production no longer authentic or valuable for reference in years afterwards.

Photographic art is distinguishable from all others in that its representations are, and ought to be, pure reflections in their ultimate issue, not manipulations; and the only credit the photographer can take, so far as art is concerned, lies in the skill with which he can conceive and arrange pictorial effects, apart from appliances beyond his sphere, such as the manipulation of composite negatives.

These are my views on this part of my subject regarding legitimate means for constructing pictorial effects and arrangement. It may be considered a mere matter of taste and opinion which I set as to the *modus operandi*. Well, I have given my reasons, and reiterate that I wish to see photographic art clearly defined from other branches, that no means be employed to lower the worthiness of what I conceive to be legitimate artistic effort, and that its special art—by simple reflection—be kept pure and as severe as possible.

I have no objections to any treatment by light on the subject proper, or on prints. This is analogous to the methods employed by the printer of etchings. There is the etching proper, but by the skill of the printer, under the direction of the etcher for completed proof, he shades certain parts by more ink being left on the surface, or keeps other parts very clean where brilliancy is required. Much may be done towards such an end in photographic printing, and I have no doubt is done, which I regard as legitimate work, because it is done purely by light.

Although double printing is almost universally employed, still I regard it as a do no better. The want of some appliance was felt when clouds and landscape could not be taken simultaneously, but now that sky-shades can be adjusted to the lens, such as my friend Mr. Parker's, of Glasgow—so thoroughly controlling the light on the sky while the landscape is being exposed first—every one who has seen his production must

feel that double printing is unnecessary. Certainly it is very tempting for composition purposes, that by choice cloud effects you can introduce lines that have a beneficial effect in composing with the landscape, yet all this is a part of the same cobbling which I complain of, and infinitely better would it be were you to bide your time and catch favourable clouds as they appear in conjunction with the landscape. Should you be pushed for time, and no clouds present when the plate was exposed, then, when the subject is printed, tone in, and graduate a sky by the influence of light over the surface, which would represent and give the feeling of a pure sky. It is to be feared that much of the indulgences in extraneous appliances is the result of doing the work by the easiest methods, irrespective of truth and taste. If there be difficulties in any department, let us fight with them, and not resort to spurious methods because they happen to be easier or more convenient.

I have always regarded photographic art and its requirements as being more allied to dramatic art than to that of fine art. For the construction of a scene, having several figures in it, see how carefully the arrangement of them have been made by actors, each individual, each group of figures, varying in position and action, and this every night reproduced because the subject has been fully felt and understood. I do hope the day is not far distant when stage effects may be photographed. Indeed, it would be worth the effort if rehearsals were made in the open air, under sunlight, and during the course of action instantaneous impressions taken; it would not only be valuable and serviceable for actors, but for all interested in dramatic and pictorial art.

In conclusion, let me earnestly urge upon all desirous of entering on this study, either from external nature or the human figure, to begin by making simple efforts on the principle of these *forte* points which I have illustrated. Have the camera focussing glass divided into odd numbers—say five or seven—and very soon you will be able to discover their value and suitability to any subject. I humbly trust the critiques I have made on the pictures brought before you may have been suggestive and profitable, and that nothing which I have said, either on the pictures or otherwise, may have been the least offensive to any of the originators.

NORMAN MACBETH, R.S.A.

Department for Inexperienced Photographers.

SILVER PRINTING.

THE above title is very comprehensive, inasmuch as there are quite a variety of methods by which silver printing may be performed. That to which we shall confine ourselves in the present article is silver printing on albumenised paper.

Albumenised paper is simply a fine quality of paper, one side of which is heavily sized with albumen in which has been beaten up a certain proportion of a chloride, such as that of ammonium. The object of the albumen is mainly to keep the picture on the surface, thereby ensuring brilliancy, for without it the photograph would be produced in the body of the paper and have a sunken, lack-lustre appearance. The object in adding the chloride is to cause the formation of chloride of silver, which is very sensitive to light, more especially when in contact with organic matter such as albumen.

As albumenised paper is now so readily and cheaply procured in commerce, and is prepared of so great excellence, it is not expedient that private consumers attempt its preparation. It is rendered sensitive by floating it for two to three minutes upon a solution of nitrate of silver in water. There is always a certain best strength of this solution, but unless one knew definitely the proportion of salt that has been mixed with the albumen, its determination is left very much a matter of doubt. For example, some albumenisers salt their paper so lightly that a silver bath containing thirty grains of nitrate of silver to the ounce of water suffices; but in the absence of definite instructions it will be found advisable to employ a solution rather exceeding, but not under, fifty grains in strength.

Having poured a sufficient quantity of such solution into a flat porcelain or glass bath, take up the sheet of paper by opposite corners, so as to form it into a curve, and place it neatly down on the solution, so as to prevent any air bubbles forming on the coated surface, or any of the silver solution to flow over its back. This must be done in a feebly lighted room, one by preference into which the light is admitted through yellow paper. Gas or candle light does not exercise any bad influence. In course of its duration on the solution the paper should be raised up by one corner by means of a pair of horn forceps, and examined to see if it is all uniformly wetted. In about three minutes it must be raised up and drawn over the edge of the dish in order to get rid of the superfluous silver solution, and then suspended to dry. This may be done either by wooden spring clips (American clothes clips), or by laying it, back down, over a stout cord stretched across the room. Pieces of blotting-paper should be placed underneath so as to absorb the drippings, and these

should afterwards be placed away so as to have the silver recovered from them.

When quite dry, the paper is ready for cutting up and being printed upon.

Let the printing be carried much farther than it is desirable it should appear eventually, as by the toning and fixing operations the print becomes somewhat reduced. After the printing has been done, place the prints, one by one, in a dish of water, each being allowed to become quite wet before the next is added. This removes most of the free nitrate of silver, which is considerable. The first washings ought, therefore, to be preserved, as the whole of the silver can be recovered, which materially diminishes the cost of outlay. The washing water ought to be changed two or three times, but it is scarcely necessary to keep any but the first washings.

The prints are now transferred, one by one, to the gold toning bath. The acetate toning bath is that which will be found most generally useful, because after it has been made it retains its good working qualities for a long time, whereas some others will not keep good over one day. The acetate bath derives its name from the chloride of gold being placed in solution along with acetate of soda, and it is better that the bath be allowed to stand at least one day after its preparation before being used for the first time. A reliable formula is—

Acetate of soda	30 grains.
Chloride of gold	1 grain.
Water	8 ounces.

After the prints are immersed in this, they will slowly pass from a rather unpleasant red tone to a violet, and afterwards a cold blue colour. As soon as they are seen to pass from the purple to the blue tone, remove them and transfer them, without washing, to the fixing bath, which consists of four ounces of hyposulphite of soda to a pint of water. In this bath they may be allowed to remain seven or eight minutes. Both in the toning and fixing baths precaution must be taken that the free action be favoured by keeping the prints in motion, and not permitting two of them to stick together, as this will cause inequality of the toning action.

After remaining for the time mentioned in the fixing bath, lift up the prints and examine each one by transmitted light, when a peculiar translucence will indicate whether the chloride has been quite dissolved out or not. Should such translucence not appear at first, return them to the hyposulphite solution for one or two minutes longer. It is inattention to the prints at this stage that is the main cause of their fading in after years.

Next place the prints in water, very frequently changed, until the hyposulphite of soda is thoroughly removed from the interstices of the paper. Some printers are so expert as to be able to ascertain this by the application of the tongue to the print, for if the soda be still present there will be a peculiar saline taste. It is well to wash them considerably beyond this stage so as to make sure. Next spread out the prints upon clean blotting-paper and remove the excess of water, afterwards hanging them up or laying them out upon a clean towel till dry.

We shall resume our remarks on this subject next week.

Is tobacco smoking in the dark room injurious to the progress of the developing of plates? asks the *Photographic Times*. One of the answers given to this question asserts that cases are on record, when negatives which had been developed without the presence of tobacco smoke had neither suffered any injuries, nor had they been improved. It is not reasonable to believe, however, that tobacco smoke will exercise no influence upon sensitive substances. The magic photographs inserted in cigar holders are developed by smoking. We are well aware of the nature of these photographic toys, but cannot dispute the fact of their development. Smoking in the dark room must have some effect; and as there is the chance that it is injurious, besides increasing the risk of a fire would it not be better to dispense with it here?

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Date of Meeting.	Name of Society.	Place of Meeting.
March 7	Notts	Institute, Shakespeare-street.
" 7	Blackburn	
" 8	Great Britain	5A, Pall Mall East.
" 8	Newcastle-on-Tyne & N. Counties	Coll. of Physical Science, Newcastle.
" 8	Manchester Amateur	Masonic Hall, Cooper-st., Manchr.
" 8	Derby	Sykes's Restaurant, 33, Victoria-st.
" 8	Bolton Club	The Studio, Chancery-lane, Bolton.
" 9	Photographic Club	Anderson's Hotel, Fleet-street, E.C.
" 10	Birkenhead	Free Public Library, Hamiltan-st.
" 10	Bradford Amateur	Grammar School.
" 10	Cheltenham	4, Clarence-street.
" 10	Halifax Photographic Club	Mechanics' Hall.
" 10	Manchester Photo. Society	36, George-street.
" 10	London and Provincial	Mason's Hall, Basinghall-street.
" 11	Ireland	Royal College of Science, Dublin.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

On Thursday night, February 24, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. F. W. Cox presided.

Mr. H. M. HASTINGS had taken home a piece of one of the white mounts spoken of by Mr. Henderson at the previous meeting as having been tested by him. He (Mr. Hastings) had taken off the three outermost layers of the card, then dipped it in litmus; it went a deep red colour, being distinctly acid. He exhibited the reddened card to the meeting.

Mr. A. L. HENDERSON remarked that he had stated that all the mounts might not be alike.

Mr. A. HADDON said that Mr. Henderson by boiling pieces of the mount in water might have boiled out a volatile acid.

Mr. E. C. CONRAD thought any acid in paper to be likely to be sulphuric acid, as that was generally used in the manufacture.

The adjourned discussion upon Mr. Hubert's paper upon collodio-chloride printing then took place.

Mr. J. HUBERT exhibited various lantern slides he had prepared by the collodio-chloride transfer process; he had found it, he said, necessary to print rather deeply to produce them. He also exhibited a variety of collodio-chloride prints upon opal glass and paper.

Mr. J. TRAILL TAYLOR, in making a few remarks on the paper read by Mr. Hubert at the previous meeting, and on some of the statements made by that gentleman in course of his demonstration, first alluded to a claim made on behalf of the printing paper then exhibited, that, unlike albumenised paper, it did not expand when placed in water. In order to test this, he (Mr. Taylor) had taken the identical sheet of paper handed to him by Mr. Hubert, and having cut from it a slip of the precise length of nineteen and three-quarter inches, had placed it in water for half an hour, when, upon again measuring it, it was found to have expanded to twenty inches and one-eighth. This fact he considered fatal to the claim made by Mr. Hubert, that the paper in question was quite free from the expansion by which albumenised paper was known to be characterised, as in this respect both were alike. Again, Mr. Hubert appeared to be pervaded by the idea that in bringing before them collodio-chloride paper he was showing them something new, whereas it was well known to most of them present, having been originally introduced by M. A. Gaudin in 1861, and reintroduced by Mr. Wharton Simpson in 1864, about which time it had been brought prominently before the world, more particularly through the Photographic Society early in 1865, where formulae had been given and specimens exhibited. Many experimentalists had at that time contributed their quota to the perfecting of the process, among which the sulphocyanide toning bath, advocated at last meeting by Mr. Hubert, had been published by the late Mr. Henry Cooper over twenty-two years ago. One of the most important improvements made upon the original formula emanated from Mr. W. T. Bovey, who at that time (1865) was an assistant in the employ of their brother member, Mr. Prestwich; it consisted in the addition of an organic acid—citric acid by preference—by which this system of printing became applicable direct to porcelain or opal plates. Perhaps the most daring improver of collodio-chloride was W. Terry, of America, who added the fulminating compounds of silver to the emulsion with an alleged marked advantage. The addition of a few drops of the supernatant solution of strong ammonio-nitrate of silver or oxide of silver dissolved in nitrate of ammonia, to which alcohol was then added and heated to the boiling point, to even a bad emulsion of collodio-chloride had by Terry been found to impart wonderful properties of fine colour and brilliance. Still others had rung the changes upon the various chlorides which were more or less soluble in alcohol. Among these were those of calcium, calcium, cobalt, lithium, magnesium, and zinc, which were all readily soluble in that menstruum, those of ammonia, barium, sodium, and strontium being soluble in an inferior degree. As Mr. Hubert appeared to attach importance to the novelty as well as the utility of multiplying negatives through the agency of collodio-chloride, he was rather sorry to have to disillusionise him also on this point. In 1869 paper prepared with collodio-chloride for this express purpose was a regular article of commerce in London, and in THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for 1870 would be found an article on multiplying negatives, by the speaker, in which were given directions for reproducing a negative in substantially the same language as that employed by Mr. Hubert last week; and the late Mr. Baden Pritchard had brought this application of the emulsion before the Photographic Society, although, for some reason unknown to the speaker, he soon afterwards discontinued its use, as did Mr. Jabez Hughes, who had made extensive preparations for working it. The whites were doubtless free from the organic salt of silver which would be found in those of albumenised prints when Mr. Spiller's suggestion of removing it by ammonia was neglected, but

in other respects collodio-chloride prints were as liable to decay as albumen prints.

Mr. HENDERSON thought it curious that a collodionised paper should have expanded to the extent mentioned by Mr. Taylor without curling.

Mr. TAYLOR had spoken of the baryta-surfaced paper before the collodion emulsion had been put on it; the paper did not expand equally in all directions; the other way it expanded about one-eighth of an inch.

Mr. HUBERT remarked that his prints did not curl in the baths to any marked extent when he worked the process at the previous meeting.

Mr. HENDERSON felt certain that collodion prints contained traces of organic salts of silver in the whites; in 1865 he had sealed some collodio-chloride prints against glass with Canada balsam, and the beautiful purple tones had disappeared in course of time. Collodion was a good preservative of pictures, provided that care were taken to choose a sample without an acid reaction, and it was especially good when mixed with varnish. Simpson's formula was good in the selection of non-deliquestent salts.

Mr. HADDON wished to know how long the emulsion would keep and how long the paper would keep with proper care, also whether it would give the same range of tones from red to blue as with albumenised paper. Why not print direct upon an opal plate by the collodio-chloride process?

Mr. TAYLOR said that when Henry Cooper introduced sulphocyanide toning in 1865, he dwelt specially upon the fact that the progress of the toning action in the print must be viewed by transmitted light.

Mr. J. J. BRIGNSHAW thought the sulphocyanide toning bath to be a very strong one.

Mr. HUBERT said that it was made from Obernetter's formula, and not that of Dr. Liesegang.

Mr. MEDLAND asked whether Dr. Liesegang had coated glass plates for contact printing.

The CHAIRMAN asked if the high gloss could be removed from the prints without injuring them.

Mr. J. B. B. WELLINGTON believed the process to be hardly suitable for lantern slides, because they could not be printed by artificial light, and even by daylight could only be produced by contact printing.

Mr. A. COWAN said that a flexible film gave good contact with the negative, and that was an advantage of the transfer process.

Mr. HUBERT turned out about one hundred and twenty prints a day, and had a quick eye for unequal expansion of papers; he had not noticed it with Dr. Liesegang's. That the paper expanded before it was coated with collodion was no proof that it did so afterwards. No, the process was not perfect when it was first brought out, and perhaps it might be followed up now. Dr. Liesegang used a treble-gummed paper for transfer purposes.

Mr. COWAN said that gum or some similar substance had been used before.

Mr. HUBERT remarked that if gelatine had been used instead of gum it would not have been suitable.

Mr. W. M. ASHMAN said that Mr. Bruce, of Dunse, Scotland, had worked the process steadily for twenty years, and was doing so now, he believed.

Mr. COWAN stated that the carbon process could be worked with equal ease.

Mr. HUBERT objected that then the progress of the printing could not be watched.

Mr. ASHMAN was aware that Mr. Baden Pritchard gave up the collodio-chloride process because carbon transparencies were more easily made.

Mr. HUBERT believed that amateurs would find it easier than the carbon process. In working the latter experience was necessary; besides, collodio-chloride emulsion would keep a considerable time, and be always at hand to turn out a print when wanted.

Mr. G. GLANVILLE had tried the process, but found that the beautiful tones passed away after a few years, and then the prints looked worse than those upon albumenised paper; moreover, the obtaining of fine tones cannot always be depended upon; sometimes the prints came out of a greenish colour.

Mr. HUBERT had met no such difficulties in toning. In testing for permanency, when the albumen print had entirely vanished in the solution the collodio-chloride print had not been visibly attacked by the cyanide of potassium, and he did not see why the protection of the image should be ascribed to the porous collodion.

Mr. TAYLOR said that the collodion resisted permeation. The really fatal thing was the internal elements of decay in the print itself.

Mr. HUBERT responded that Captain Alney had collodio-chloride prints which had been kept under a variety of conditions since 1869, and were still as good as ever; not one of them had altered in colour or in the purity of the whites. Persons had failed with the process, but then some operators were not as good as others. Collodio-chloride prints had been exposed outside his house under similar conditions to albumenised prints which had been properly toned, fixed, and washed, and the latter prints had in the course of a winter and summer exhibited beginnings of decay, but the collodio-chloride prints had not done so.

Mr. TAYLOR had seen certain albumenised prints exposed in a New York show-case in 1879 which were in the same good condition when he saw them again a few months ago, and New York had a more trying climate than Hackney.

Mr. HUBERT responded that New York was dry and Hackney was damp, and damp was a great enemy to photographs. Chloride of strontium was sparingly soluble, and chloride of lithium was very soluble in collodion. Moreover, because of its very low combining number, lithium would carry a great deal more chlorine than an equal weight of most other metals. Dr. Liesegang said that the reason why his paper did not curl was, that he coated it while it was tightly stretched upon a frame, and then he dried it quickly. He (Mr. Hubert) had tried a few experiments, and found that the use of two drachms of glycerine to the pint of emulsion greatly reduced the curling propensities. He thought that he could tell how ordinary paper was prepared to take emulsion, but would not do so that evening. He had printed direct on glass by the process, but then the progress of the printing could not be watched so easily, unless a special printing frame were used. He stated that any range of tone can be obtained with the sulphocyanide bath; the acetate bath does not work so well, and requires deeper printing. He believed that he should

always keep the collodio-chloride process more or less in use, and that by it he could depend upon turning out a hundred successive proofs without a failure.

A vote of thanks was unanimously accorded to Mr. Hubert.

The question was asked, "Should not photographers protect themselves against firms working enlargements for the profession, and exhibiting same as their own work and as photographers to the public, thereby obtaining business by selected works of those who support them, at prices far below those of professional photographers?"

Mr. ASHMAN said, "Boycott them."

Mr. COWAN thought that no firm acted as stated.

Mr. GLANVILLE knew that it had been done, and such firms had the pick of the work of the very best photographers.

Mr. HENDERSON considered that such action would be a betrayal of confidence.

Mr. ASHMAN believed that the system had long existed.

Mr. GLANVILLE recommended that work should be withdrawn from such photographers.

Mr. CONRAD said that the enlargements were the own work of the photographers in question.

Mr. COWAN remarked that Mr. Haddon had said nothing, but he knew what Mr. Haddon was thinking. Mr. Haddon was thinking that photographers who had enlargements done for them by others often exhibited them and charged for them as their own work, and probably the picture had been worked up to something far better than the original negative would naturally give. The argument cut both ways. Mr. Haddon thought that photographers should make their own enlargements.

The proceedings then closed.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting was held in the Technical School, Bridge-street, on Thursday, February 24.—Vice-President J. W. Harrison, F.G.S., in the chair.

The minutes of the last meeting having been read and confirmed, Messrs. Hoskins and Leeson were duly elected members.

In answer to a question, Mr. A. PUMPHREY said four-inch condensers were the best size to use in lantern work; and as to the question, "What is the exact position to place the diaphragm in the lens?" Mr. E. C. MIDDLETON said experience should decide. Mr. B. KARLESE recommended the perusal of Dallmeyer's book on lenses, which gave precise particulars on the subject.

The Lantern Committee gave their report on the results of the prize competition.

The next business was the development trials. Four plates each of Ilford ordinary and rapid were exposed in Warnerke's sensitometer, and developed with pyro and ammonia, oxalate, an American developer, and Beach, by Messrs. Delicate, Nock, Middleton, and Pickard, the results as to speed of developing being respectively Beach, pyro, American, oxalate. The rapidity of the plates shown by the numbers of the sensitometer showed nearly as high on the ordinary as on the rapid; in fact, one seemed as good as the other. On showing the plates in the lantern, those developed by Beach and pyro were denser in tone, and those by oxalate and the American developer rather better balanced gradations.

After some discussion, and an exhibition of a number of lantern slides brought by members present, the meeting was concluded.

The next meeting is on March 10, when the American slides lent by the Camera Club will be exhibited.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES' PHOTOGRAPHIC ASSOCIATION.

THE ordinary meeting was held in the College of Science, Newcastle, on Thursday, the 10th ultimo.—Professor Herschel in the chair.

After the usual routine business, Mr. J. PIKE, the Hon. Secretary, read some notes on *Orthochromatic Photography*, and showed some specimens of work. At a recent meeting, during the discussion on orthochromatism, Mr. Pike suggested collodion as a solvent for the dye used, eosine, or erythrosine, &c. He had since made what he called orthochromatic collodion, with which an ordinary gelatine plate was coated, dried, exposed in the camera, and developed in the usual way. They have answered very well, and the plate was rendered more sensitive to gaslight. To get the best orthochromatic effect it was necessary to use yellow glass behind the lens. The gelatine plates used in conjunction with the collodion were the Ilford, and Mr. Pike said he could confirm Mr. Leon's statement as to the rapidity of these plates even compared with those prepared and tested by gaslight.

A discussion followed, Messrs. Herschel, Gibson, Sawyer, Downey, and others taking part.

The next meeting will be held at the Literary and Philosophical Society's Institute, the occasion being the lantern slide competition.

CAMERA CLUB

THE meeting on Thursday evening, February 24, gathered to hear and discuss a paper sent by Mr. J. F. Mostyn Clarke, entitled *Art and Photography—Portraits*. In the absence of the author, the paper was read by Mr. W. A. Greene. Mr. D. P. Rogers occupied the chair.

Previous to the paper of the evening being read, Mr. W. K. BURTON, by the desire of some of the members, brought up the following subject:—He said it was known that a most unwarrantable attack had been made in one of the photographic papers (*The Amateur Photographer*) upon Mr. J. Traill Taylor, in connection with the address he had delivered at the Camera Club Conference. Some indignation had been felt at the reflections cast upon Mr. Taylor personally, and in regard to the paper he had read. In consequence, a letter had been written and signed by such members of the Committee as were available

at the time. This was sent to the paper in question, but was refused insertion, and it was now considered desirable for several reasons that it should be read at one of these meetings of members. Mr. Burton then read the letter, which ran as follows:—

Camera Club, 21, Bedford-street, W.C., February 15, 1887.

SIR,—We, the undersigned members of Committee of the Camera Club, request the insertion of this letter in your next issue to protest in the strongest terms against what we consider the unwarrantable attack made upon Mr. J. Traill Taylor in the account of the proceedings of the Camera Club Conference, contained in your last number. Mr. Taylor was specially asked by the Committee to read a paper at the Conference, and, far from thinking that the Camera Club was "slighted" by the paper he did read, we consider that he brought before the meeting, in a thoroughly practical manner, matters of real importance to amateur photographers, the solution of the difficulty of enlarging with ordinary coal gas, and without expensive apparatus. There was nothing that could be likened to the manner of a manufacturer's representative in the way in which Mr. Taylor brought forward the subject.—We are, Sir, yours truly (signed), GEORGE DAVISON, W. K. BURTON, W. H. HYSLOP, A. R. DRESSER, E. FERRERO, JOHN B. CAMPBELL, H. J. GIFFORD, WALSBY GREENE, J. FRANCES COLLINS, D. P. RODGERS.

The meeting having heard the letter, agreed in the advisability of including it in the reports of the proceedings.*

On a call from the CHAIRMAN for objects of interest, Mr. Gifford exhibited a new three-fold stand, and Mr. W. K. Burton showed some interesting examples of reversal of image sent to him by Mr. Lewis, of Hove, Brighton. By exposing an ordinary dry plate for a few seconds to diffused daylight under a negative, and then developing in the usual pyro developer, a negative nearly as good as the original was obtained.

Mr. A. R. DRESSER stated that by long exposure he had produced, with a dry plate, a positive from a positive without development, but doubts were entertained as to the accuracy of this statement.

Mr. Rodgers showed three interesting photographs done by Mr. Blanchard from twenty to thirty years previous. One, a silver print, having shown signs of fading, had been treated with mercuric chloride, and had stood unchanged ever since. Another was mounted on card with a lithographic tint, the character of this surface being, perhaps, accountable for the perfect preservation of the photograph, which had undergone trying treatment and exposure to damp. The third was a carbon print, also in a perfect state of preservation.

Mr. W. ASBURY GREENE then read the paper on *Portraiture*, sent by Mr. Mostyn Clarke [see page 135], calling attention at commencing to the following additional introductory remarks sent by the author:—

I am very conscious, in attacking and endeavouring to treat with brevity and simplicity so vast a subject as art—even in its relations to photography—how inadequate the work done must be; but my object is not to accomplish the work myself, so much as to enlist the thought and study of others. I allude to the introducing among photographers higher knowledge and standards in art than at present exist. Photography is the means—or might be the means—of making art possible in many a home where greater works, even in black and white, are now an impossibility. The existing state of things—perhaps I ought to say, as I see it—is anything but satisfactory. Why does one turn away in despair from the majority of photographic windows, and from a large proportion of the pictures in our exhibitions? Because of a violation of the laws, often the earliest and simplest, resulting from a want of true feeling in art in some, and more frequently through imperfect study. The want of artistic excellence in pictures, it is fair to say, is often due largely to the nature of the papers upon which they are printed; for example, how much real feeling can be given to albumen prints—a most unsympathetic medium from an art point of view? Then platinotype, possessing most qualities wanting in albumen, is in the hands of all, save a few, sadly wanting in warmth of tone. Again, looking to the quarters where excellence is, we find it with men whose work is not given to the public, except in a very few instances; thus failing to touch the source of existing evil. To be personal: I have attempted to begin the alteration of this state of things in two ways; one, by the formulation of art elements; the other by technical improvements in the printing of results. Of the former the paper to-night is a part, and I venture to hope that the work I have endeavoured to begin will be seriously continued by others, and will be taken up by some of those amongst us who are far more competent to complete the task than I myself am to commence it.

In discussion, Mr. S. B. WEBBER thought a reflector was of great importance, but it was possible to have too much of a good thing. It was not pleasant, after using a looking-glass or a reflector, to find a portrait of yourself and camera included in the particular picture you were taking.

Mr. W. TOMLINSON had read it suggested in some art journal that photographers would find success easier in groups than in single portraits, because some at least came out well, and were satisfied.

Mr. F. G. SPIERS had taken his own portrait by setting the camera before he went to bed at night, so that he was being taken before he awoke. The feeling that the photographic eye was upon him prevented him sleeping, and at seven he rose and put the cap on, exposing again later on. He expected to come out twins, but the photograph was not bad, only a little corpse-like.

Mr. G. DAVISON criticised the examples sent by Mr. Clarke as to composition and expression, and asked Mr. Burton what were the difficulties in the way of obtaining plain non-albumenised sensitised papers.

Mr. BURTON said the plain sensitised papers could not well be preserved, but must be used freshly made. They were also difficult of preparation. He thought the ammonio-nitrate process the only suitable one. He considered that Mr. Mostyn Clarke's paper was a very valuable one, and that his portrait examples showed much skill.

Mr. A. DEED suggested a special exhibition, no retouching to be permitted.

Mr. E. FERRERO believed portraiture not worth anything without retouching, because of defects, such as freckles, &c., being intensified in photography.

* In order that our readers may understand this matter, we may explain that some one connected with the contemporary named, apparently ignorant of the fact that an enlargement could be made by means of common gas, wrote in it a silly paragraph of a somewhat personal nature. As an erroneous opinion was entertained by a few that the journal in question was in some way or other the organ of the Camera Club, or, at any rate, in rapport with it, the Club lost no time in repudiating a connection which, if it ever existed, certainly has no existence now, and of which the leading members have expressed a feeling of shame, bearing in mind, as they do, the avowal of the promoters of the contemporary that "no dry scientific details" of photography would ever find a place in its pages. The Camera Club now has its own organ, issued monthly to its members, and it, together with the Club itself, has our best wishes for its continued prosperity.—EDS.

Mr. BARCLAY had heard it affirmed that if the plate were exposed through the glass back these defects were overcome.

Mr. J. J. ROBERTS had not been satisfied with his results at portraiture on orthochromatic plates by artificial light.

Mr. RODGERS thought albumenised papers suitable for portraiture and the gloss a distinct advantage for small sizes. He would glaze these highly—treat them as gems—to get all the light possible into the details. "Lighting was a very great point in portraiture, and he had found the best reflector to be a large white cardboard placed as near as possible to the sitter without being in the field of vision of the lens. With a looking-glass as reflector he had got a double set of shadows. Referring to Mr. Barclay's remarks, he would observe that taking the portrait through the back of the plate would give a reversed picture in the print. The two sides of the face were never alike, and the nose never in the middle of the face. He had been very well pleased with the behaviour of orthochromatic plates in taking portraits by gaslight.

Mr. H. J. GIFFORD referred to the necessity of having the surroundings suitable to the subject if it were intended that the portrait or figure study should also be a picture.

On March 10 Mr. Norman Macbeth, R.S.A., will deliver a lecture on *The Composition of the Pictorial*, with lantern illustrations.

BOLTON PHOTOGRAPHIC SOCIETY.

ON Wednesday evening last week, the fifth annual *soirée* of the Bolton Photographic Society was held in the Baths Assembly Room, Bridgenan-street, when the attendance of members and their friends numbered about four hundred. The walls were hung with photographs taken by members of the Society.

The PRÉSIDENT announced that the prizes had been awarded as under:—No. 1 Competition, "Photographs taken during the season," 1, Mr. E. N. Ashworth, Turton, *Norwegian Curio*; 2, Mr. C. K. Dalton, *Oht School, Winwick*. No. 2 Competition, "Photographs taken at any outdoor meeting of the Society in the past season," 1, Mr. C. K. Dalton, *Boat House, Worsley*; 2, Mr. William Laithwaite, *Whalley Abbey*. No. 3 Competition, "Transparencies," 1, Mr. Jabez Boothroyd; 2, Mr. W. Laithwaite.

Mr. B. H. ADAMT, the Secretary, read the annual report, which regretted that the Council could not congratulate the members on an increase of the Society, but its finances were still satisfactory. During the summer months open meetings had been held at several places, and the operations of the Society had been very successful.

Over a hundred views were then thrown upon the screen by Mr. J. H. Leach, while Mr. R. MENGER described the pictures.

The proceedings were enlivened with music by the members.

LIVERPOOL ANATEUR PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of this Association was held on Thursday, February 24, at the Royal Institution,—The President, Mr. George H. Rutter, in the chair. The minutes of the previous meeting were read and confirmed.

Mr. James Lahy was unanimously elected a member of the Association.

The SECRETARY read a letter from Miss Calder, Hon. Secretary of the Re-creative Evening Classes Association, asking the assistance of members of the Association in making a series of lantern slides from photographs or drawings illustrative of the reign of Queen Victoria, with special reference to the Jubilee year.

Mr. Lange showed a very fine enlargement in gelatino-bromide of two dogs.

Mr. Atkins exhibited a print which eighteen months ago had been fixed in hypo in the usual way and then merely rinsed in water and dried without any washing. The print was in apparently as good condition as it ever had been, showing no appearance of fading through leaving the hypo in.

The Secretary exhibited a number of whole-plate negatives on Eastman films taken during his visit to Norway last August; also some attempts at collotype taken on an autotypist by floating the gelatine sheet on potassic bichromate solution, printing when dry under a negative, and, after soaking in water, printing with an ink roller.

Mr. LANGE also showed and explained the use of the "gelatine skins" for Eastman's "stripping films," and Dr. Kenyon showed a negative mounted on the gelatine film.

Mr. J. E. Thornton, of Manchester, then exhibited his patent Jubilee camera, tripod, and roller slide.

Mr. GEORGE H. RUTTER then read a paper on *Odds-and-Ends*. He referred first to the various makes of films, exhibiting specimens of Stebbing's, Warnerke's, and Pumphrey's improved films; he also showed the carriers of Messrs. Warnerke, Pumphrey, and Morgan & Kidd. He next mentioned the desirability of being provided with several convenient pieces of minor apparatus on a tour, instancing a compass, view meter (of which he showed specimens of Harvey Barton's and one on the principle of a monacle opera glass, also a combined focuser and view meter), and bayonet joint fitting to the lens. He then gave an account of some experiments to ascertain the value or otherwise of various baths preparatory to development. He exposed Eastman paper films upon the Atkins's sensitometer, which consists of gradually increasing thicknesses of tissue-paper mounted on a large sheet of glass, so that it can be placed in a window; the small stop of the lens was used, and five seconds was the exposure. Four exposures were made as rapidly as possible, and then each plate was cut into two, making eight pieces, and were divided into two lots, one to be developed with ferrous oxalate and the other with pyro. The first of each lot was dipped for one minute in a fifteen-per-cent. solution of common table salt, the second one minute in a half-per-cent. solution of hypo, the third in half an ounce of the American standard alkali solution in three ounces of water, and the fourth received no preparation. They were then developed for five minutes, fixed, and washed, and the results exhibited to the

meeting. Mr. Rutter then referred to Herr Göllecke's article in the *Photographische Mittheilungen* on a preliminary bath of very weak hypo. His conclusions were that the sensitiveness of the plates is not increased but the time of development shortened, which result seems to be confirmed by Mr. Rutter's experiments.

Mr. W. A. WATTS read *A Few Words on Orthochromatic Photography*. He said he had no intention of producing a paper, as his experiments had not been sufficient nor successful enough to warrant his doing so; but when he found the meeting was to be disappointed, through illness, of a promised paper, he thought a short account of his attempts might fill the gap. He had met so far with very little success, due, firstly, to endeavouring to work without a yellow screen, and, later, to the want of keeping powers in the sample of commercial plates he was trying. This was said to be a fault in all the commercial plates, but Mr. B. J. Edwards had stated his plates would keep for twelve months. He next tried dipping some plates in a bath of eosine and drying, and found that with the yellow screen the exposure was increased about twelve times; and although there was no very decided orthochromatic effect, the negative and print therefrom compared with those obtained with a plain plate seemed to have gained immensely in vigour and contrast. He next referred to the processes published by Messrs. Hyslop and Wellington for dipping in a bath containing erythrosine and silver, and expressed the fear lest these processes should be held to interfere with Messrs. Taillier & Clayton's patent. He advised members desirous of experimenting to try Ives's chlorophyl process, of which he gave some particulars.

Mr. A. W. BEER moved a resolution, which was carried, that the various photographic journals received by the kindness of the several editors be placed in a protecting case and laid on the table at each meeting.

HALIFAX PHOTOGRAPHIC CLUB.

THE monthly meeting was held on the 24th ultimo in the Mechanics' Hall,—The President, Mr. Councillor Smith, in the chair.

Two new members were elected and another nominated.

There was a large attendance of members, and a very instructive evening was spent discussing the claims of platinotype, the Eastman bromide paper, and carbon, to be permanent processes. The matter being of great interest, it was decided to take a whole evening for the separate discussion of each process, Mr. George Hepworth to give a paper and demonstration of *The Platinotype Process* on March 24; Mr. B. Rowley, *The Eastman Process*, on April 21; and Mr. W. Clement Williams, *The Carbon Process*, on May 26.

After some expression of opinion in reference to the use of a preliminary bath of weak hypo to development of under-exposed plates, it was thought to be of little or no practical utility, and although prominence was being given to the subject in some quarters just now as something new, it might be classed as a rediscovery of an old method.

There were some sample negatives from orthochromatic plates laid before the Club alongside with similar subjects taken on ordinary plates. The chief advantage seemed to be in the rendering of the blue and violet, and very little gain, "if any," in yellows and browns, the test being a graduated and numbered range of colours supplied by a Berlin wool pattern card.

Correspondence.

AMATEURS AS ARTISTS.—LENSES.

To the Editors.

GENTLEMEN,—I was much amused, and much more puzzled, on reading some remarks by Dr. Jacobs during a discussion at the Photographic Society of Leeds. He said, "The amateur has great advantage over the professional man in being able to invest his subject with artistic attractions." I think there are some professional photographers who have some knowledge of art. If not, perhaps Dr. Jacobs will kindly name a few amateurs to whom they could apply for lessons. I am sure there are some very clever amateurs, but by far the largest number have very little knowledge of how to make an artistic picture. He also says he "pities the fate of the professional, doomed to photograph the miserable specimens of humanity—the incarnation of ugliness." I am sure the professional must feel grateful to him for his sympathy, and will no doubt appreciate it highly; but I fail to see in what way he has such a fearful doom. Perhaps Dr. Jacobs will kindly explain. I am always anxious to gain information.

The other remarks of the Doctor with regard to the value of having several lenses on his Swiss tour are much more sensible. May I inform him that on my annual visit to that country I take about twenty lenses for the various sizes of negatives? For stereoscopic pictures I use three pairs of single landscape, two pairs of rectilinear, and one pair of rapid rectilinear. For cabinets and 9 × 7 negatives I find it necessary to take four single, two rectilinear, and three rapid rectilinear lenses. Of course all these vary in focus from three inches to twenty. One remark I may add, and that is when straight lines are not in the views, I always use single landscape lenses.—I am, yours, &c.,

W. ENGLAND.

RETOUCHING.

To the Editors.

GENTLEMEN,—All employed as retouchers will agree with Mr. R. Barrett's remarks in last week's number of this JOURNAL, about the question, "How many heads has he done to-day?" and with your permission I should like to draw attention to another point concerning *employés* and employed relative to retouchers. You will generally see in advertisements the phrases, "Wanted, a retoucher; none but competent men need apply. Only those that can do best work," &c.

But are they willing to pay for competent men and best work? The wages usually paid are two pounds per week. Is this a sufficient remuneration for an *artist* (who in most instances is really the chief means of making the business pay)? He is expected to make every defect in the negative right, and is compelled to sit all the weary hours of the day trying to get on with the bulk of the work, and wondering how long his eyesight will last, to enable him to keep on with this tedious work. Would it not be only fair to pay competent men and for best work double the amount now given, and to state the salary in the advertisement?—I am, yours, &c.,

OVER-WEARY.

Liverpool, March 1, 1887.

T. R. WILLIAMS AND RETOUCHING.

To the Editors.

GENTLEMEN,—In the method of retouching by Mr. R. Barrett, page 117 of THE BRITISH JOURNAL OF PHOTOGRAPHY, he certainly makes a great mistake in stating that Mr. Williams retouched his negatives, and this brought him into vogue before other photographers began.

On the contrary, Daguerreotypes secured him royal patronage before he began collodion work. I distinctly remember the time when ladies of title daily flocked to his residence in Southwark to be photographed. This was before he built his West-end studio, and when he carried on his work of Daguerreotype slide making in an extemporised conservatory. I pointed out some time since to another correspondent that his success was in the lighting of his subjects, reflecting screens and blinds being freely used.—I am, yours, &c.,

H. J. GOUFIN.

A DARK ROOM LAMP.

To the Editors.

GENTLEMEN,—I have for some months past been using a lamp which I designed for use in the dark room, and as I have found it very useful when travelling I have much pleasure in bringing it under the notice of your readers.

It consists of a lower portion about six inches in diameter and one inch in depth, the top, which is somewhat smaller than the bottom (so as to be contained in it when the lamp is closed), is connected with the bottom of the lamp by a spiral spring, one end of the spring being fastened to the top the other to the bottom portion of the lamp, and is surrounded on its outer surface with transparent material. I have found three thicknesses of yellow tissue-paper do very well.

When in use, and the spring expanded, the lamp, which is circular in shape, is twelve inches high and six in diameter. To close the lamp pressure is made on the top, the spring compressed, and the top is by this means brought into contact with the bottom, and is held in this position by some small fastenings. It then occupies a space of about two inches in depth and can be easily carried in a bag or portmanteau. I have arranged with Messrs. Wratten & Wainwright for the manufacture of this lamp, and it can be seen at 38, Great Queen-street, W.C.—I am, yours, &c.,

February 28, 1887.

AMATEUR.

LIMELIGHT MATTERS.

To the Editors.

GENTLEMEN,—A few words in reply to Mr. G. R. Baker. I am glad to learn that the price of gas in bottles is to be reduced, and presume the house gas will be reduced in proportion to fourpence, as its cost is almost *nil* against twopence per foot for making the oxygen. If so, that will bring the cost of twenty feet of mixed gas down to 8s. 4d., and will reduce the discrepancy, but a great deal will still remain. He does not really answer my question about the regulator, however. What I asked was not if it worked "*perfectly*" in any general sense, but this specific point: If I put it on a lantern and turn the jet *entirely off*, does the regulator still prevent any extra pressure passing it, or does it then gradually pass and blow off the pipe or burst it (unless strong and well secured)? I have seen several in my time, but all necessitated turning off at the valve if the jet was quite turned out, and what I wanted to know was, whether or not this regulator did the same.

I was not so discourteous as to question Mr. Baker's figures in any way, except in the modified sense that an operator need not *necessarily* spend so much on bag plant as was tabulated. If you use bottles, &c.,

you *must* buy everything; there is no choice. But many a lecturer has made his own boards. I said nothing at all about boards "first-class, with prop," &c., but merely upon the much simpler plan I described, and which I have proved to be most thoroughly efficient; indeed, I much prefer solid boards to those made with bands, as they use more of the gas and get more pressure at the finish. I am a little surprised at what almost seems his imputation that I got some poor carpenter to make the set "at a venture," &c., especially considering what follows, and must ask leave to state the facts. My own boards were originally a pair of *single* ones from Darker's. When I adopted mixed gases, I added the third board and legs myself. Later on, changing for larger bags, I employed the "carpenter" referred to, to alter and enlarge these same boards, legs, &c., which he did, and I simply paid him what he asked for this job when done. He is not a mere journeyman, though he started as such; but beginning with one, has now two shops and a thriving business as decorator, repairer, and upholsterer, and ought to know what he is about. After his enlargement was done and paid for, and with the boards actually before us, I asked what another pair made right out would be, for a friend, and he replied, "Somewhere from sixteen to eighteen shillings." That is all I know about it. But in any case, I am somewhat surprised that Mr. Baker should venture upon such a supposition without any possible knowledge of the circumstances.

And still more am I surprised at what follows. "I think Mr. Wright will call to mind that the price of prisms he mentions in his valuable work on *Light* is certainly not commercial if a fair quality is supplied." Here, again, I state the facts. Wanting a prism rather suddenly, years ago, I went into the shop of Messrs. Newton, in Fleet-street, then as an utter stranger and chance customer. I went there simply because on my sole former visit for a tin of limes I had seen a shelf full of prisms in a glass case. I purchased two different ones at the retail prices marked thereon, one of which was as described, and at that time there were at least half a dozen similar in the case at the same price. It was the first and only shop I entered for the purpose, and what I wrote some months after was, that such a prism "could be bought" for the price I had paid, 4s. 6d. But "quality," says Mr. Baker. Well, what I published reads, "Of course such a prism is not optically faced, but only polished like lustres; but it is good enough for most screen work." And so it is. As I do not know Mr. Baker, and never had a word with him as far as I know, I was astonished at his apparent assumption that I know of something to the contrary of this. On inquiry, I learn (for the first time) that he is the representative of Mr. J. H. Steward, and upon that I do remember that Mr. Darker has called upon me, stating that Mr. Baker's firm were unable to procure such prisms as I had described at the price. I took a little trouble over the matter then, on account of Mr. Darker, and ascertained that the supply I had seen were now exhausted, and there was a difficulty in exactly replacing them; but I found Messrs. Newton could still supply a long prism at 8s. 6d. (which, by two cuts, would furnish *three*), very slightly less in face, but of *better* quality and *better* polished; they also supply a slightly smaller prism, fairly polished, for 5s. What I wrote, therefore, still holds good. Prisms of this sort are, of course, not supposed to go through several optical hands, but if wanted, should be ordered direct of dense flint from the flint "lustre" makers, in a small quantity at a time. That is my personal experience which Mr. Baker says I shall "call to mind;" but I do not think it justifies his inference at all. And how I am to know what a prism of a certain common and cheap sort, described as such, "can be bought" for, further than by what it costs me haphazard, in one of the best shops in the city, I fail to see. Had the price been double, I should have paid it just the same. It is no part of my business to run down prices; and although more than one person in the optical trade has been kind enough to place me practically upon "trade" terms, in return for various little matters in which they are good enough to consider I have at times assisted them, as it is a pleasure where possible to assist any one, I have never on any occasion quoted such "prices" to any one else, but have always taken care to ascertain what the usual retail price would be.

Coming back to the main question, one statement of Mr. Baker's I do very much question, that to the effect that the light from bottles is "far in advance" of that from bags. It has often been made since Mr. S. Highley first made it, but I have often seen bottles used and never seen it verified. With one qualification, perhaps: if some old-fashioned jets are used, "hung up" with useless packing, great pressure may produce a better light. But with our modern jets, possessing large chambers and a clear passage, I have yet to see their light with bags surpassed from bottles. I am, however, not only willing, but very desirous, to be convinced, since, as the Editors know, I have very solid reasons for wanting to get on polariscope, and especially microscopic work, the *very utmost light* a line can give; and if Mr. Baker will let me know in advance of any occasion on which he is about to do his very best, if I possibly can I will be there to learn a lesson, and will own up that his light is better than mine, should it be so, as unreservedly as I now take leave to doubt it. My own experience and belief is, that more than a certain pressure makes a jet roar and does not give more light, and that very often the fourth half-hundredweight gives no advantage until nearly the end.—I am, yours, &c.,

LEWIS WRIGHT.

P.S.—Since the above was written and posted, I have called again on Messrs. Newton, and find I misunderstood the price of their smaller prism.

This is really 3s. 6d. and not 5s., the last being the price of right-angled prisms as required for another experiment I describe. They further now say, that if there is any preferential demand for the larger size I describe at 4s. 6d., or any decent order for it from any one, it can be supplied to sell retail without any difficulty, of better quality than I bought and wrote about. I also find that their ordinary retail price for large double pressure boards, made either solid or "skeleton," as good as it is possible to make them for any practical purpose, is very far indeed under four guineas. Mr. Baker's may possibly have more work or material in them; but I was remarking on necessary outlay only. I did not even remember his name, but only his figures, and had not the least idea that he had any business interest in them.

March 1, 1887.

L. W.

AUTOCHROMATIC COLLODIO-GELATINE PLATES.— A SUGGESTION.

To the Editors.

GENTLEMEN,—There appears to be a difficulty about using eosine on gelatine plates on account of patent rights. Used in collodion there are no patent rights to contend with. I therefore venture to suggest that eosine be incorporated with the collodion emulsion in suitable proportions, and then, to gain greater sensitiveness, pour on a rapid gelatine emulsion as a preservative; let it rest on for a few seconds, and then drain off. In June, 1885, the question of increasing the rapidity of collodion-emulsion plates by means of a preservative of gelatine emulsion was brought into notice in THE BRITISH JOURNAL OF PHOTOGRAPHY by Mr. Ernest Graham and myself, and I shall be glad to see other experimenters take this process in hand with the addition of eosine.—I am, yours, &c.,

G. V. J. POIRIN.

Streatham, February 23, 1887.

P.S.—The plates after washing can be dipped in the eosine solution before treating with the gelatine emulsion.

STRIPPING FILMS.

To the Editors.

GENTLEMEN,—An article in the issue of the JOURNAL of the 4th instant contains a statement so utterly at variance with my own experience, as well as that of numerous friends using the Eastman stripping films, that I am constrained to take exception thereto and to state the facts as I have found them, for the benefit of any who may feel inclined to use these films.

The article, in speaking of "the old method of transferring the film," says, "After the negative is developed, fixed, and washed, it is, while still wet, squeezed down upon a glass plate which has previously been coated with a thin solution of indiarubber and dried." Thus far good, but the following is in direct variance with my experience, extending over the past year, and a very considerable number of exposures and developments: "The negative is then allowed to dry, and it is imperative that it becomes perfectly dry, otherwise the next operation—the stripping of the paper backing—will fail."

Now all of my not inconsiderable experience points to the exact opposite of this. I have invariably found that if the negative be allowed to dry thoroughly, it will not strip. The soluble layer of gelatine becomes insoluble, and the paper backing utterly refuses to part from the film. This is the case whenever pyro development has been employed. With ferrous oxalate no such result need be feared, and the negative can be stripped whenever desired. A marked case confirming this statement occurred to me this very evening. A week or two since I developed from exposures from a roll of films made in October last. They developed most beautifully, and were duly washed and squeezed upon rubber-coated glass plates. In less than fifteen minutes afterwards, one of these plates was placed in a tray of hot water, and almost at once the paper backing left the film of its own accord and floated on the surface of the water. The plate, with the film attached, was transferred to a tray of cold water, a thin skin of gelatine floated over it, the whole removed from the water, gently squeezed, and placed in a rack to dry. The following morning the film was easily stripped from the plate, and a negative of surpassing beauty and perfection was the result.

But what as to the other three? The hour being late and rest desirable, I left them in the rack to become thoroughly dry, intending to do so to-night, failing most lamentably. The paper backing utterly refused to part from the film, leaving the glass only in company with the latter, to the utter ruin of all three negatives. This has never occurred when I have stripped the films before the latter were quite dry, and I may add that this is also the experience of the manufacturers at Rochester.—I am, yours, &c.,

W. H. WALMSLEY.

De Lancey-place, Philadelphia, February 18, 1887.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, March 9, will be on *Old Dry Plate Processes*.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column: but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Wanted, backgrounds, burnisher, or studio accessories, in exchange for new treadle sewing machine, cost £8 10s.—Address, PHOTOGRAPHER, 45, Chester-street, Wrexham.

Wanted, good ferrotype specimen pictures, quarter-plate or larger; exchange, nitrate of silver, sewing machine, banjo, &c.—Address, CONFECTIONER, 9, Market-street, Exeter.

Abney's book on Emulsions and other photographic literature; exchange single lens or good instantaneous shutter.—Address, COUCH, 6, Berkeley-street, Piccadilly, London.

Will exchange a musical box, eight airs and three visible bells (new), for a 8½×6½ Swift's rapid paragon lens or other noted maker's.—Address, W. H., 16, Rosemount, Douglas, Isle of Man.

Will exchange a fifty to fifty-six-inch tricycle, latest style, for a Dallmeyer's rapid rectilinear lens, size from 12×10 to 15×12, sliding tube or rack and pinion.—Address, JOHN BAXTER, 47, Methley-road, Castleford, Yorkshire.

15×12 landscape camera wanted in exchange for carved oak table (cost £7), gas heating stove, balustrade, grass mat, backgrounds, &c., or exchange for 15×12 group lens by a good maker.—Address, J. HOLLOWAY, 138, Amlerley-road, S.E.

Weston's champion burnisher, patent six-inch roller, and battery of nine gem lenses, in exchange for wide-angle rectilinear lens, whole-plate, by good maker.—Address, F. JOHNSON, Photographer, 68, Strand-street, Douglas, Isle of Man.

Will give tricycle, or Monle's Photogen, or one of Wrench's new patent "Metamorphiser" lanterns, or patent air brush, for a bi- or tri-unial lantern (first-class), or modern portable tourist's whole-plate camera and lens, complete. Difference adjusted.—Address, VINCENT HATCH, Ilkley, Yorkshire.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

R. STEELE.—We are not quite sure, but we believe the gentleman uses a portrait lens of long focus.

V. C. YEULETT.—The address of the Willesden Paper Company is Willesden, Middlesex. They will forward you a price-list on application.

BEGINNER asks: "Is there any means of getting rid of the scratches, &c., that invariably come upon the faces of the sheets of ebonite used for drying paper negatives?"—There is no way that we know of removing scratches except by the resurfacing of the ebonite. With care in using scratches will not be formed.

A. WELLS writes: "Could you enlighten me as to how the image is produced on the stone and stock for printing in printers' ink? also if there is any book published on the same?"—Our correspondent should obtain Mr. Wilkinson's book on Photo-mechanical Processes. It may be obtained through any of the stock dealers.

GREENHORNE.—The double combination can, as you are aware, be used for portraiture; but the back lens, as shown in your drawing, is misplaced—that is, reversed. The front lens can be utilised for landscape work by serving it in place of the back, or placing a stop, not exceeding one-fifteenth of its focal length, one and a quarter inch in front.

J. S. N. says: "I have, unfortunately, in bringing my negatives down here spilt a lot of glycerine over some of them; could you tell me of any means to get this out of the film again?"—The glycerine may be removed by copious washing. If the films show a tendency to blister, the glycerine can be got rid of by washing it out with methylated alcohol.

E. HILL writes: "Will you kindly give me a little more of your valuable information? I have a Ross' rapid symmetrical lens, and I find it impossible to take views and interiors in confined situations. Can I make it do so? if not, will you kindly advise what lens to get for that purpose?"—Our correspondent had better procure a portable symmetrical lens of a much shorter focus, so that a wider angle will be embraced.

J. E. GOWER writes: "I have some silver which is useless to me in the metallic state, and I shall be obliged if you will tell me—1. If I can convert it into nitrate pure enough for emulsion purposes?—2. If I should proceed in the same way as in making gold chloride, using, of course, nitric acid only?"—1. Yes.—2. Dissolve the metal in dilute nitric acid—one part acid to two of water—and then crystallise as in making chloride of gold.

G. R. E. asks: "Can you inform me, through your 'Answers to Correspondents,' where the baryta-surfaced paper for collodio-chloride printing, as recommended by Mr. J. Hubert in last week's BRITISH JOURNAL OF PHOTOGRAPHY, can be obtained? I have experimented considerably with this process but always failed to get a suitable paper."—In reply: A suitable paper for the process is supplied by Mr. E. Liesegang, of Düsseldorf.

ORTHO (Wylde Green) says: "I notice in some of the reports of photographic meetings members say how many dozen different kinds of eosines and erythrosines there are to be had, and that only a very limited number will do for orthochromatic plates. Can you give an address where beginners can get the above dyes so that they may be depended upon?"—Messrs. Hopkin & Williams, Cross-street, Hatton Garden, supply a suitable eosine and erythrosine.

A. LEVY (University Club) asks: "Would you kindly tell me if a special lens and very special knowledge are wanted for photographing oil and water colour pictures, engravings, sketches, &c.? Also, if a special lens is wanted for platinotype work?"—In reply: No special knowledge or appliances are requisite. In the case of coloured pictures, however, better effects will be obtained by employing orthochromatic plates. No special lens is required in platinotype work.

NO NAME.—1. By distilled water is meant water obtained by the condensation of steam. 2. If the albumen be well whipped up with a little ammonia, and then allowed to subside, it may be used for spotting purposes. 3. The reason why the prints show a "milky haziness" when removed from the toning bath is that the silver was not washed out before its immersion. 4. The same developer is used as for ordinary. The difference, if any, in the exposure required in the two makes of plates can be ascertained by experiment.

HALF-PLATE writes as follows: "Will you inform me through your 'Answers to Correspondents' which is the best kind of tricycle, or the make which photographers mostly go in for? I intend to use a half-plate camera, and I thought you would perhaps know which would be the easiest and most suitable, or the make generally adopted by photographers."—It is very much a matter of taste, and different photographers have different opinions on the matter. Any good machine to which the apparatus can be conveniently attached will answer.

BROMIDE asks: "Will you kindly tell me the cause of small black specks which completely cover the enclosed two lantern slides? They are from collodio-bromide emulsion of my own make. I have got these minute specks in making the last two or three batches of emulsion; but I have had them before, but could never account for them. You will notice them much better with a focussing glass held up to the light."—The spots appear to be coarse particles of bromide. No doubt a more careful filtration of the emulsion will get rid of them.

NED-REB writes as follows: "In making neutral oxalate of potash with carbonate of potash and oxalic acid, I inadvertently poured two or three drachms of sulphuric acid into the solution instead of two or three drops. Will this exert a bad influence on the enlargements (bromide) I intend to develop?"—Our correspondent does not say to how much oxalate solution he has added the sulphuric acid. A comparatively large amount of acid may be added without doing much harm except making the developing action very slow. A single trial by the development of a print will settle the question.

REV. W. D. writes: "In your 'Answers to Correspondents,' will you please tell me how I can get a white porcelain dipping bath chemically clean? I have used it once or twice for the hypo bath (indeed, it was bought for that purpose), but I am now anxious to use it for a silver bath. I do not like to risk a silver bath until I feel certain it is free from hypo. How can it best be eliminated?"—The best plan will be to fill the vessel with dilute nitric acid—one part acid to fifteen or twenty of water—and then allow it to stand for a day or so. If the glaze be good, as the bath has only been used once or twice, simply well washing with water should suffice.

A PUZZLED ONE writes: "1. For some time I have had a difficulty in getting my prints to tone, i.e., they are painfully slow in toning. After reading this year's ALMANAC I concluded my chloride of gold was at fault, and seeing an article by Mr. T. Forrest on making one's own, I tried the same, following out his instructions implicitly; still my toning bath is not improved. I use acetate of soda—about forty grains to one grain of gold.—2. Should the toning bath be distinctly alkaline? I use ready-sensitized paper."—In reply: 1. We strongly suspect, under the circumstances, that the paper must be at fault. Better try another sample.—2. Neutral or slightly, only, alkaline.

E. DUDLEY says: "Will you please answer the following questions in your 'Answers to Correspondents'?"—1. I had some of England's intensifier made up the other day according to the directions in this year's ALMANAC, and on putting a plate into it found that it did not intensify at all in spite of leaving it in for about thirty hours. Can you account for this?—2. I had also Beach's developer made up. This also would not work, but think this was perhaps due to the pyro solution being wrong. I added one ounce sulpho-pyrogallol (Platinotype Company's). I think this cannot be enough. Please tell me if it is so, and whether it would prevent the image from appearing at all. Can I remedy it now?"—In reply: 1. Probably your correspondent omitted to treat the plate with the ammonia after the mercuric solution.—2. Better make up a fresh solution.

SULPHUR writes: "Can you kindly inform us the cause of the spots on the enclosed print? We have been troubled with similar ones lately on several prints out of a batch. We have tried every means to cure same—different batches of hypo, different brands of paper—but to no purpose, as a certain portion of the prints is sure to get them; sometimes when we take them out of the washing trough, other times after they are mounted or being enamelled. We also discarded the zinc trough, we washed in and used porcelain dishes and pans instead, and still they come. The only cause we can assign for them is that it must be sulphur in the albumen of the paper or else some injurious matter in the water of this town. If it was the latter, why should only some be so? We would be glad of your opinion on the subject."—The spots are clearly due to sulphur, arising, probably, from air bubbles adhering to the surface when they are immersed in the fixing bath; or, may be, when they are removed from the hypo into the first washing water.

ORTHO writes: "1. Some time ago I sensitised some paper according to a formula given in the JOURNAL a few months ago, a second bath being used of citric acid, gum arabic, &c. After using the acid bath a few times it becomes discoloured as the silver bath does. Is there any way of clearing it?—2. I have a French lens which does not seem quite satisfactory somehow. If I were to send it to you would you examine it, and say if it could be improved by any means?—3. If all the waste solutions containing silver, such as hypo baths, pyro baths, old toning baths, &c., are put together, will zinc deposit all the silver, and how long does it take before all the silver is deposited?"—1. When the citric acid bath becomes discoloured, fresh should be made. It is not expensive.—2. Send the lens here.—3. Zinc will reduce the metals contained in the solutions. The time required for their reduction will depend upon the temperature. The higher it is the sooner will the action be completed. There is no silver to be reduced in the old pyro developer for dry plates.

Der Amateur Photograph is the title of a serial issued by Ed. Liesegang of Düsseldorf, the first monthly number of which we have received. It contains several articles of a class intended specially for amateurs. It is printed in German.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.—Mr. Hubert writes to say that, as he would like to introduce a measure of reform in the working of this Association, he requests those in favour of such alleged reform to meet him at 181, Aldersgate-street, E.C., on the evening of the 24th instant.

The fine photographic and scientific collection of Mr. Edward Viles is advertised for sale on this day week. Mr. Viles having given up country life in favour of London, finds his whole time so absorbed with his literary work that he has resolved to distribute his entire collection of photographic appliances.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next ordinary meeting of this Society will be held on Tuesday next, March 8, at eight p.m., at the Gallery, 5A, Pall Mall East, when the discussion will be taken on the paper read by Mr. J. B. Spurge at the last meeting, and a paper will be read by Mr. H. P. Robinson on *Exhibiting and Exhibitions*.

A HAPPY suggestion was made by Mr. Edgar Clifton at the North London Photographic Society on Tuesday evening. It had reference to the temporary shutting off the light from the screen on which photographic transparencies were being projected by the lantern, to prevent the act of substituting one picture for another from being seen. The suggestion is to employ an ordinary pneumatic single or double-flap shutter, the pneumatic ball being placed between two small bellows-shaped boards, and in such a position on the floor as to be easily pressed by the foot of the lantern operator during the moment when a fresh slide is being pushed forward in the carrier.

UNDERWOOD'S CAMERAS.—Mr. J. Solomon, 22, Red Lion-square, has afforded us an opportunity of carefully examining the most recent designs of the Underwood Camera, for which this firm is the London agent. It is a camera that is both easily and quickly set up, and which will stand much tear and wear. There are certain mechanical features in its construction which tend to lightness and rigidity, and to facility in working. The manufacturers are E. & T. Underwood, Birmingham, and some of its features are patented.

In the Photograph and Record Department, in charge of Sergeant Thomas H. Adams, are preserved about 60,000 portraits of between 6000 and 7000 criminals. Many of them have been received from other cities, and are not included in the Rogues' Gallery, which contains the busts of the "best people" arrested in New York. When a professional is photographed, fifty copies of the negative are taken, and the "pedigree" of the person printed on the back of each copy. One copy is then despatched to each precinct, where the pedigree is entered on the Record Book, and the picture placed in the Rogues' Gallery, as at headquarters. The remainder are retained for the use of officers, and for exchange with the police authorities of other cities. Gallery and Record Book are the patented inventions of Sergeant Adams. Portraits of deceased criminals are removed from their infamous companionship, as are those of the four per cent., more or less, of living ones who turn from their evil ways when young, and by years of well-doing entitle themselves to this favour, which is granted at their own request, seconded by that of reputable business men. Should they relapse, their portraits are returned to the case.—*Harper's New Monthly Magazine*.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1401. VOL. XXXIV.—MARCH 11, 1887.

ORTHOCHROMATIC PLATES BY SOAKING.

SUCH considerably divergent opinions have been expressed by different experimentalists with regard to not only the effect produced by soaking plates in solutions of eosine or erythrosine, but also as to the keeping qualities of plates so treated, that in the course of our own experiments we have given some attention to an attempt to find where the discrepancies lie. As a result, we are inclined to name as the cause the method adopted in soaking the plates; and though we cannot go so far as to say that this constitutes the sole cause, we have proved by actual trial that it is possible by treating portions of the same plate in a different manner with the same solution to produce entirely different results.

It is not our intention here to speak of any particular solution or formula, but simply of the mechanical application of *any* of the solutions recommended for the purpose, whether the treatment consists of a single or a double operation. Our remarks, therefore, may be taken as referring to all.

In the first place, let us suppose a plate plunged direct into the optical sensitising solution; the first and most important point to see to is that the film be thoroughly and uniformly imbued with the solution. This depends of course upon the length of time the solution is allowed to act, and the latter, again, varies with the character of the film treated. Thus a film consisting of soft gelatine will absorb the solution more rapidly, and perhaps, also, more uniformly, than one in which a harder gelatine has been employed or chrome alum has been added. Some films, too, show a persistent "greasiness" upon wetting, especially where no ammonia is used in the solution, and may be soaked for a long time before the liquid runs in anything like an even manner from the surface.

Until this occurs it is scarcely possible to hope for uniformity of action, and if the soaking be prolonged in either the colouring solution or that of silver nitrate sufficiently long to produce that effect, then it is probable that the photographic or orthochromatic properties of the plate may be injuriously affected. We would recommend, then, that the plate be first soaked in distilled water until the film is thoroughly softened, and the water runs evenly over the surface without streaks or grease-like markings. When the latter occur, a broad camel-hair brush passed over the surface will prove an assistance, or, better still, a pad of picked cotton wool thoroughly wetted may be applied with some force until the water takes "kindly" to the whole surface. In some cases, especially when the film is composed of a particularly hard gelatine, or the plate has been long prepared, it may be advisable or necessary to render the water very faintly alkaline with ammonia, or where the latter is objectionable a small

quantity of glycerine may be added. In either of these cases, however, a final rinse in plain distilled water should be applied before immersing the plate in the colouring or colour-sensitising solutions.

The film after this treatment is in a condition to absorb whatever subsequent solutions are applied to it more uniformly, though less rapidly, just as a plate soaked in water before development develops more slowly, though with greater regularity. It will also permit the superfluous liquid to drain away more evenly without standing in beads or drops; though in order to promote absolute uniformity we prefer to pass a very soft, pure black rubber squeegee *once* over the surface of the plate, and so remove all superfluous solution. The camel-hair brush or pad of cotton wool are objectionable for this purpose, as they are apt to leave the solution in streaks.

Another advantage of the preliminary soaking, and perhaps the greater, is that any soluble matter that may exist in the film through imperfect washing of the emulsion is by this means eliminated, and so cross actions are prevented. Slight traces of soluble bromides or nitrates in a film plunged directly into the colouring solution would no doubt exercise some influence of one kind or another; but, whether beneficial or otherwise, it is better removed, as likely to lead to uncertainty in using different batches of plates. Another substance likely to be found in some films is chrome alum, and this, too, would be advantageously removed without destroying the effect for which it was originally added to the emulsion. In fact the preliminary soaking in distilled water seems calculated to give us a cleaner and purer basis to start upon.

In conclusion, we reiterate that it is more than probable that many of the discrepancies in the results that have been reported from soaked plates are traceable solely to the method in which the soaking has been performed, as we can ourselves vouch that very different effects are frequently given with the same plate when the preliminary soaking is omitted.

MARVELLOUS things have been effected by micro-photography, but there is a limit to the degree of diminution attainable, this arising from the silver of which the image is formed being deposited in coarse granulated particles, that is, coarse from a microscopist's point of view. Where exceedingly fine writing or drawing for microscopic examination is required then must the services of the diamond point be had recourse to. These remarks are *apropos* of our having met, the other day, the venerable Mr. W. Webb, one of the earliest members of the Photographic Society, but better known in connection with his marvellous skill in producing microscopic writing. A slide which he had just executed, and which he favoured us with, contains the Lord's Prayer written so small as to require an eighth of an inch power on

the microscope to see it. The best way to convey an idea of the dimensions of the writing is to say that if a square inch were written over with letters the same size, the whole of the Bible and half a Bible more could be contained therein in quite legible form, this being equivalent to five millions of letters. Photographic reduction could not, of course, approach this, even within almost immeasurable distance. Mr. Webb designates this latest effort of his as a Jubilee slide.

It appears to be a popular fallacy with a certain number of photographers, that portraits enlarged from small negatives are, of necessity, free from distortion. Many imagine that a portrait which is first taken on a small scale, and subsequently enlarged, must always be less distorted than if the picture were taken direct. This however does no necessarily follow, for under some conditions the direct picture may be the less distorted of the two. For example, if the original negative be taken with a short focus lens placed very close to the sitter, which is frequently the case in taking small portraits, a certain degree of distortion is introduced. This, though not conspicuous to the casual observer while on the small scale, often becomes painfully so when the picture is amplified. Here is one of the reasons why enlargements sometimes fail to please the sitters and their friends, though the small original was considered satisfactory, while they may be unable to point out a definite reason for dissatisfaction.

In taking a large portrait direct, if a long focus lens be employed so that the camera can be placed a great distance from the sitter, there will be little or no distortion. The great mistake in taking large direct heads, as we have frequently pointed out, is that of using lenses of far too short a focus. In the old wet collodion days, lenses of large angular aperture were almost imperative, but it is not so now. Gelatine plates when employed with lenses of long focus and comparatively small aperture, require far less exposure than used to be necessary when the collodion process was worked even under its most favourable conditions. Large heads can now be taken direct without difficulty, and, to all intents and purposes free from distortion, provided a lens be used of sufficiently long focus to permit of the camera being planted at a considerable distance from the sitter.

ANENT the article last week *On Business Matters*, a correspondent in the country writes, denying that the same "seedy state of things" which he says reigns supreme in most London studios exists to the same extent in country ones. This we can confirm, for we know that, as a rule, the higher class of studios in provincial towns, particularly in seaside places and holiday resorts, are far better cared for than are those of a corresponding status in the Metropolis. If the whole of the discarded properties and backgrounds which are totally unusable, owing to their being out of date or too dilapidated, which are now crowded up in corners in many studios were eliminated, and only those in actual use retained, the room would really look better furnished, and also present a more modern appearance generally. Here is a hint for the coming season, to all whom it may concern.

WHAT has been said with reference to the studio and other departments of many establishments, applies with equal force to the outside specimen frames. If half the pictures exhibited in some show-cases were removed, the remainder would prove attractive. A few faded or yellow portraits in antiquated costumes, interspersed amongst others which are fresh and in modern attire, are quite sufficient to leaven the whole batch. At the entrance to what, a few years back, used to be considered one of the leading West-end establishments, are to be seen some specimens which were produced probably some fifteen or more years ago by its late proprietor. The photographs are yellow and fading, and are in the old-fashioned *passee-partouts*. The only merit these pictures ever possessed was, that they were somewhat large for the period at which they were taken. These photographs appear to quite overpower some really good work of smaller dimensions of a modern type which is in close proximity.

MARCH is not usually looked upon as an unpropitious month for photography, so far, at least, as fogs are concerned. This year,

however, it has opened, as February closed, with a succession of foggy days such as few remember to have seen before at this season. The fogs have not been confined to the Metropolis alone, but have been pretty general throughout the kingdom. On several occasions they have been accompanied by sharp frosts, which have produced some excellent hoar-frost effects, and some admirable photographs of them have been secured. Occasionally at this season some charming frost pictures may be obtained, but they must be taken pretty early in the morning, because, when the sun breaks through, its heat quickly causes the sparkling crystals to disappear; hence the artist who wishes to secure this class of picture must be on the alert at this time of the year.

NOTWITHSTANDING the advantage of the electric light to those who possess it, in bad weather it is not always the photographic panacea that many are led to believe. In dull weather, or when there is no natural light whatever, the electric light is satisfactory enough. But when a dense fog pervades the studio it is found, in practice, that brilliant negatives cannot be obtained unless, indeed, the camera be brought very close to the sitter. This entails the employment of a short focus lens with its concomitant evils, which the most skilful retouching fails to remedy. Obtaining satisfactory negatives through twenty feet or so of a genuine "pea-soup" London fog—however many thousand candle-power the electric light may be—is not an easy thing to accomplish, as all know who have made the experiment.

ECHOES FROM THE SOCIETIES.

"THE negatives turned out nowadays are not worth calling negatives at all." Such is the dictum of a professional platinotype printer, and I could not help calling it to mind a short time since, as I looked at a wet-plate portrait negative taken many years ago by a first-rate professional. There is something about the look of a good wet-plate negative that altogether puts gelatine in the shade; but for printing results I am bound to say the statement I have quoted is not only too sweeping, but is far from the mark. My own opinion, that the work of the best gelatine men is equal to that of the best collodion men, while, if we go to inferior workers in both classes, the gelatine work will be, out and out, the better. I know one amateur of eminence who, though he had worked collodion processes for years, never turned out a presentable picture, except in his own estimation, until he took to gelatine; another, who had exhibited good collodion work unsuccessfully on many occasions, but took a prize the first time he exhibited gelatine.

But Mr. F. M. Edwards, when he made the statement, was speaking in connection with the platinotype process, which, he says, requires good negatives, those by the wet-collodion process being the best. Undoubtedly the process requires, in order to produce the finest results, not only a "good" negative, but a good negative of a certain class—dense, and with plenty of gradation from almost absolute opacity to clear glass—just the type of negative that was more frequently found in the wet-collodion days than now. But I deny that it is impossible to produce such with gelatine, or that it is more difficult in competent hands. Perhaps the reason such negatives are not more common nowadays is that tastes have changed in such matters.

With regard to the discussion that has been going on as to the permanency or otherwise of collodio-chloride prints, I think as much may be said as in connection with ordinary albumen pictures. One, like the other, may be permanent—that, is reasonably so—or it may not, according to circumstances. A year or two after the first publication of the process I saw some positives on opal in the studio of an artist of repute that had been produced in this manner, and which in the short time since their production and under favourable circumstances for keeping had faded from their pristine purple tone to a sickly brown, highly suggestive of sulphuration. On the other hand, a few months ago I came across, in the portfolio of a friend, some collodio-chloride prints on paper, which, from their tone and the purity of the lights, might have been executed yesterday, though, my friend informed me, they were at least fifteen years old; and a couple that had been hanging for several years on the walls of his study

appeared in nowise different. It is possible the opal glass might have exercised a baneful influence in the one case, but the other seems to me to prove that collodio-chloride prints need not necessarily fade.

But there is another possible reason for the difference, though it is with something like fear and trembling that I mention it at the present time, since the practice is coming into vogue again. I allude to the employment of the sulpho-cyanide toning bath, which was in great favour for collodio-chloride pictures in the early days, and is now in equal repute for gelatino-chloride. About the same time, too, the sulpho-cyanides were recommended as substitutes for hypo as fixing agents, and I remember somebody spoke of them as "the fixing agent that will not fix." Perhaps the sulpho-cyanide fixing bath might have been the delinquent.

The Cellierier mechanical colouring process received a good advertisement in rather gushing language in a report of the Birkenhead Association some time ago; but although the advertisement tells us what it will do up to a certain point, it says not one word as to how it differs from a score—nay, at least, a hundred—of similar methods, patented and unpatented, that have seen the light during the past few years. The poikelograph, crystoleum, oleotint, and any number of others have, in turn, "glittered like a meteor" and then—"gone."

In reading through the weekly reports of the meetings throughout the country, one cannot help being struck with the vast change that is going on in favour of practical and useful demonstrations. Time was when the monthly meeting of a Society formed a convenient opportunity for professionals to meet and talk business matters, and amateurs to compare notes and results; and if any one read a paper on "A Trip to the Land of Goshen with the Camera," it pleased the author no doubt, and was accepted by the company assembled as a matter of course—a part of the day's business, in short. I don't object to the "Where-to-go-with-the-Camera" style of lecture if it is illustrated by means of the lantern, and the lecturer is not too diffuse in his descriptions of the scenes displayed; but, I think, even lantern entertainments are better unaccompanied by any formal "lecture;" the name of the view and any information, historical or interesting, that can be conveyed in a few words, without delaying the entertainment, are, to my mind, quite sufficient. As a proof of how photography has advanced the lantern in favour, I notice that out of nine meetings reported in one week, no fewer than six were "lantern" meetings.

Under the head of practical demonstrations we may fairly class any actual exhibition of the working of a process, whether new or old; and these are, I fancy, what are most wanted nowadays by the vast number of new recruits in the photographic army. Though there are innumerable hand-books and guides to the science, few, if any, go sufficiently into minute detail to bring matters within the comprehension of the complete tyro; besides which "an ounce of practice is worth a pound of theory;" and in the course of half an hour's demonstration a novice may pick up more than he could in a year's reading.

As a contrast to this style of filling part of an evening's meeting, I may briefly refer to a paper on an art subject read before one of the oldest societies in the kingdom, by one who has hitherto figured as a chemist. Such feats of word-playing as "the monochromatic studies of *mens* and lens" may be ingenious, and perhaps interesting to the immediate friends of the author, but to parody a well-known saying, "*Ce n'est pas la photographie.*"

Before leaving the question of practical demonstrations, I would point out an instance where such would be an advantage. At the last technical meeting of the Photographic Society another long discussion took place on the subject of orthochromatic photography, in the course of which it transpired that while some found orthochromatic plates of the greatest use, others could derive no benefit from them. One section found the yellow screen absolutely necessary to success, others invariably worked without it. Then again, though some who had successfully prepared and used orthochromatic plates found they would not keep, one, at least, of the speakers avowed that they would keep as well as others. Patent rights were then touched on. But it is, of course, impossible to enter on a practical demonstration on such a subject except in a court of law. Still I would suggest that the conflicting parties in the technical part of the question should appoint a night to "have it out," or try and convince one another, though I am afraid that some of them, though forced by the circumstances of the

occasion to "comply against their wills," would "remain of the same opinion still." But that would not matter much so long as the lookers-on had the dust wiped from their eyes.

By the way, alluding to Mr. Debenham's remarks as to the German method of examining applications before granting a patent, how is it that, though Messrs. Tailfer & Clayton were refused protection for their invention on the ground that it was not new, a patent was subsequently granted to a German for what appears to be substantially the same thing? MONITOR.

ON THINGS IN GENERAL.

I AM rather surprised at a certain important statement made by Professor Stebbing having been allowed to pass without comment, seeing that it appears to enable us to view the eosine patent in an entirely new light. He informs us that in 1877 he prepared gelatino-bromide plates with emulsion that had been dyed with eosine, he preparing the plates, and M. Ducos du Hauron supplying the dye. The centre upon which the whole subject turns is the publicity of this treatment. If it was publicly known in 1877 or 1878 that eosine was used in combination with gelatino-bromide emulsion, I think it may be taken as a fact that the Tailfer & Clayton patent, dated several years subsequently, is not worth the paper it is written upon, unless there be in it a special claim for a combination of ammonia and eosine used with the gelatino-bromide.

Mr. Albert W. Scott's hints upon the use of coal-tar colours are decidedly useful, and collodion, as he justly states, is infinitely superior to varnish for producing a coloured film upon glass. This explanation he offers of the change of colour in a varnished film may be supplemented by the statement that, as varnish is often made of the coarsest samples of methylated spirit, the impurities in that spirit may be the cause of a change of colour from red to violet, as it is a fact well known that aldehyde—a frequent accompaniment of such spirits—rapidly changes magenta into an excellent blue, and thus a strong magenta solution, partially altered, would appear violet in colour. Further, with regard to the dyeing action upon gum arabic, so far is it from being the case that such gum is not dyed by coal-tar colours, that I may say gum solutions of the dyes are not infrequently made by adding spirituous solutions to strong acacia mucilage, and well stirring the whole; the colour leaves the spirit and attaches itself to the gum, from which it is not separated by dilution with water. Mr. Scott is a practical man, and his lantern articles abound with useful hints. I should be very glad if he could tell me where to obtain the stout white drawing paper, six feet square, that he speaks of, as four feet nine inches is the utmost width I have ever been able to meet with, and I have tried many places. A six feet sheet of paper would be very useful to me for certain purposes.

I see in a recent number of this JOURNAL an account of the photographing of a bullet after being fired from a rifle, its velocity at the time being about a quarter of a mile in a second. There is no doubt that even in these days of dry plates and drop shutters this is a marvellous feat, compared with which the photographing of the "Flying Dutchman" at express speed is mere child's play. But—"history repeats itself"—I should like to ask whether something quite as wonderful was not done nearly three decades ago when dry plates were not? Was not a bombshell in flight taken by means of a *Skafé's Pistolgraph*, as the remarkable little instrument was euphemistically called?

Again may I say, "History repeats itself." Some considerable interest has recently been created by the introduction of an "iris diaphragm" to photographic lenses. I do not know how long such a diaphragm has been used as a microscopic adjunct, but I have a most distinct recollection of seeing a photographic lens fitted with a diaphragm of similar, or equivalent, construction close on a quarter of a century ago, so that it is scarcely just to speak of it as a "recent" introduction.

I noted, as did Mr. England, the droll utterance of Dr. Jacobs at the Leeds Society meeting. Of course, as regards the necessarily brief abstracts of the many Society meetings recorded in these columns, it is easy to understand how difficult it must be to give a correct *précis* of each speaker's words; but it is not easy to imagine what else Dr. Jacobs could have said at all like the words attributed to him,* than which

* See Dr. Jacobs's letter of explanation in another page.—EDS.

words nothing could be more absurd, "The amateur had a great advantage over the professional photographer, in being able to invest his subjects with artistic attraction." Whatever his ability to impart such increased attraction may be, he is too modest to make a point of frequently exhibiting it in his works, and I must say that the logic that deprives a man of his powers of artistic expression the moment he becomes a professional is of a very halting character. It is also news to me that the professional has daily presented to him a series of "miserable-looking specimens of humanity, generally incarnations of ugliness."

If ever a need for the enactment of a particular clause that appeared in one of the abortive copyright bills, to the effect that no picture should be exhibited without the exhibitor's permission, was proved, it was in the letter to the Editors by a correspondent, "W. C. B.," replied to in the last number for February. This fellow actually asks for advice from the Editors how to proceed when "people object to what they term being 'stuck up' in a show case," for, he says, "a photographer cannot be expected to be always changing his specimens merely to suit whims and fancies." These are the men who are a disgrace to the profession. "Whims and fancies," forsooth! I think the above initials must be wrongly given—C. A. D. would be nearer the mark. It is difficult to keep one's patience; I wonder how the Editors manage to keep theirs. However, of course, if they said all they thought there would soon be an end to the "Answers to Correspondents" column, for which I should be sorry, as it is a constant source of interest and amusement to me, as also are certain portions of the advertisement pages. The latest cutting from the latter that has gone in my cabinet of curiosities is an advertisement that runs—"45 Warnerke.—An emulsion maker, who can with certainty produce plates of the best quality giving above number, will be disengaged," &c. Such a man has no right to be disengaged, he is too valuable to lose. My Warnerke is only marked up to 25, as are those of most of my friends, and to think that 45 can be obtained raises a feeling of the intensest wonder as to how it is done.

What a capital lecture was that recently delivered by Mr. J. Traill Taylor at the Society of Arts! There are few who cannot learn something from it; and his description of the various modes of finding the focus of a lens is a capital summary. But, as a matter of fact, who, out of the thousands possessed of a camera and lens, ever is wise enough to ascertain for himself the focus of his lens or lenses? Very, very few, I am certain. Yet the process is very simple. For the average photographer who cares little for optics and will not go to the least trouble for finding the foci of his lenses, I am inclined to think the method given in THE BRITISH JOURNAL OF PHOTOGRAPHY a few years ago is the simplest and easiest yet given. One had to hang up a two-foot rule and observe the size of its image when the camera was at a certain distance away. This size marked on paper with a pencil was compared with a series of lines given in connection with the article, and the focus was read off at once out of the table given with these lines. Here was no trouble worth speaking of. All that was necessary was to have the JOURNAL at hand.

FREE LANCE.

BICHROMATED GELATINE EMULSION PAPER.

BEFORE proceeding to a description of the developing operation I should like to interpolate a few remarks which further experience with the Obernetter paper have led to.

In my previous article I spoke of the occasional adherence of the print to its original support if too long exposed in the printing frame. This danger, I find, is far greater than I at first found, especially when chloride of sodium is added to the sensitising solution, as the colour of the sensitive surface is then so light that the solar influence penetrates too readily through the whole depth of the comparatively thin layer of emulsion; and in the case of a negative combining delicate half tones with strong shadows, it is difficult to secure the former without rendering the latter adherent. In this case, though portions of the image may develop successfully, the film will be torn on stripping away the paper. With thin negatives offering little contrast, and using a very weak sensitising bath—not more than one and a half per cent.—the development is easy, provided the printing be performed in a weak light, and its progress carefully watched, which is easily done

on the pale yellow surface. When the half tones of the picture are just visible it is done.

I also mentioned that I had not tried the effect of sensitising without the addition of salt, but I have now done so, and find it an improvement, inasmuch as while it lengthens the exposure, as I had expected it would, it naturally lessens the danger of printing through to the insoluble substratum. In this case, however, the bright scarlet colour of the sensitive paper quite masks the faint brown image produced on the plain yellow surface, and consequently renders the timing of the exposure a matter of guess-work, unless an actinometer is used. So great is the difference between the two forms of paper, or, rather, of sensitising, that a sheet, one half of which was dipped for an instant into the sensitising bath containing chloride, after immersion in plain bichromate in order to discharge the red colour, developed successfully, so far as the scarlet portion was concerned, though the other half tore away with the paper, the parti-coloured sheet having been exposed as a single print.

The method I mentioned casually as giving promising results, that in which the emulsion paper is blackened by exposure to light before bichromatising, appears to me now to be the best of the three; the very much darker colour of the layer of gelatine retards the penetration of the light, with very much increasing the exposure as compared with the scarlet form; while, in addition to that, the combined action of the light and free silver upon the gelatine-itself colour the latter, and so add greatly to the face of the image produced. The body of gelatine is quite sufficient, but it is so weak in silver as compared with a negative emulsion, that after development, when the silver haloid alone forms the image, it is absolutely necessary to resort to heavy intensification in order to secure sufficient force even for opal work. But the preliminary exposure to light not only darkens a portion of the haloid, leaving the rest *in situ*, but it also stains the gelatine itself, without in any way rendering it insoluble, and so produces an image of ample strength for opals or for transparent positives, to be transferred to paper or backed up with any white material.

It may be noticed that the image produced by this last method, if dried when the glass picture comes away from the hot-water bath, presents, when placed in contact with a sheet of white paper, precisely the appearance and, it may be presumed, the composition of an untuned and unfixed print made upon Obernetter paper in the ordinary manner, *minus*, of course, the unconverted haloid. Its colour is a bright red, verging between those peculiar photographic nuances described from their character as "brick," and "cherry red," tending, however, more in the latter direction. Here, then, is a chance of making opal positives of the true "photographic purple" tone by simple gold toning, and without the slightest suspicion of any lurking sulphur compounds to cast a doubt on their permanency, for no hypo is used in the process. True chromium salts are said to have a clinging love for gelatine paper, and especially opal, but I do not think that would seriously affect the permanency of even the tone, and not at all the picture itself. All the carbon prints, I fancy, that I ever saw, which have shown changes of colour under the influence of time, were early single transfer prints, executed perhaps before the danger of lurking chromium salts was suspected.

But to proceed to development. Let the requisite glass supports be prepared before commencing to manipulate the prints. If opal, in the case of "matt surface" it will only require carefully cleaning, though a thin layer of hardened gelatine will be no detriment. If the opal be smooth, *i.e.* polished, the substratum is absolutely necessary. If the prints are to be retransferred from plain glass to paper the former must be prepared with French chalk and coated with collodion, after which it is washed free of the ether and alcohol and left in cold water until wanted. If to remain permanently upon the glass, as in the case of a lantern slide, the French chalk is omitted and a coating of collodion, or gelatine and chrome alum, applied alone.

In connection with lantern slides a few words may be said with regard to the preparation, both of the tissue and the mounting glasses, in order to secure neatness and to have the picture in a proper position on its final support. Let the pieces of tissue be cut very accurately, and considerably smaller than the regulation size of lantern slide. Supposing the opening in the finished slide to be two and three-quarter inches, whether square or circular let the actual mounting mask (or one identical with it) be employed as the "safe edge." Let

the pieces of tissue be cut accurately to three inches square, and let a similar-sized opening be ruled symmetrically about the aperture in the safe edge. This will leave a protected margin of one-eighth of an inch all round the picture, while there will be a similar difference between that and the glass to allow for expansion of the paper when wetted. This is of great importance, as if the paper extend over the edge of the glass the picture is sure to come away in development. For the rest, in placing the tissue in the printing frame it is only necessary to place the safe edge correctly upon the negative, the tissue upon that, its edges coinciding with the ruled lines; and finally, before squeegeeing the tissue on to its glass support to see that it is exactly in the centre, and, in fact, as carefully placed as if you were mounting a print. This being done, the finished picture will be straight and central.

The first operation in development is to immerse the exposed tissue in cold water until perfectly limp, or nearly so. With ordinary carbon tissue, in consequence of its considerable thickness, this requires some little time, but with our present paper a few seconds suffice. If too short a time be allowed it will not be flat on the glass; if too long, it will not adhere through the subsequent operations. The best plan is to just immerse the glass support, and then, plunging in the tissue, bring one edge into proper position, a little within the corresponding edge of the glass plate. As soon as the paper seems about to lose its tendency to curl, or a little before, draw the glass out of the water with the paper in contact, and, if there are no creases or folds, lay it down on a smooth table, cover it with a sheet of bibulous paper, and that again with a piece of American or waterproof cloth, and pass the squeegee over it several times, gently at first and afterwards with more force, finally placing it under pressure. If several prints are to be developed they may be placed successively in a pile, with a sheet of blotting-paper intervening; or if only one or two, a screw printing frame may be used.

Allow the prints to remain under pressure for at least a quarter of an hour, then place them in a dish of cold water for a few minutes. This is more necessary than with ordinary carbon tissue, as, owing to the short immersion before squeegeeing and the non-permeability of the Obernetter backing, there is not sufficient water contained in the sensitive film to cause it to dissolve readily and evenly if at once immersed into warm water.

After soaking in cold water for five minutes they may be transferred to water at about 100° Fahr., from which they are taken one by one into much hotter. It is impossible to name the best temperature, but I find with this paper it must be high, as, owing to the reasons I have already given, the paper and glass do not readily separate at a low temperature. Three or four minutes in the hot bath may elapse before the paper begins to show signs of moving, but it should not be hurried. When the gelatine appears to be melting at the edges, try gently with the fingers if the paper will *slide* upon the glass, but do not be rough. When this stage is reached raise one corner of the paper, and, still under the surface of the hot water, slowly but steadily peel it off. Then lay the glass in another dish of cooler water and proceed with another.

The development is by no means finished, perhaps scarcely commenced, for the image will in all probability at this point be perfectly invisible, hidden by a hopeless-looking smear. It is desirable, however, to allow the gelatine to soften thoroughly in cold or tepid water before proceeding further, and the whole of the print to be developed may be brought to this stage before going on to the next. No harm is done by leaving them to soak, but the subsequent operations are greatly facilitated.

When the whole of the prints have been stripped, the first one is taken and again immersed in hotter water, say at about 120° Fahr., and moved about that the softened gelatine may be removed from its surface. Gradually the high lights of the picture will be seen as clean glass, and when all appears clear and bright a rinse under the cold-water tap will finish the operation, and so with the rest.

If on attempting to strip off the paper, supposing the soaking in cold, tepid, and warm water to have been sufficiently performed, the film should tear, it is evidence of over exposure. Frequently the sky of a landscape will remain adherent to the glass, while the rest of the picture goes away with the paper. If the paper strips without

difficulty, and the subsequent treatment leaves little or nothing on the glass, under exposure is the fault.

If the developed image is to remain on the glass on which it is, nothing remains except the toning, of which, however, in connection with these thin films, I am not in a position to speak in this article. Before proceeding to that part of the subject, I wish next week to refer to the method of making an emulsion and coating paper, which removes all the trouble arising from the insoluble substratum of the Obernetter paper. I hope then to be able to deal with the toning and finishing.

I have devoted more time and space to this subject than at first I intended, but in my renewed experiments I have discovered in the process possibilities I had not previously suspected, and that must therefore be my excuse.

H. Y. E. COTESWORTH.

PORTABLE DARK TENTS.*

WITHOUT placing on record any chimerical suggestions for an entirely new form of tent, let us try and see if we cannot improve upon the old one, at any rate, so far as the present occasion serves, to the extent of its carcase. I am confident that a thoughtful commercial attempt to remedy the defects I have pointed out would meet with success, for there is no doubt that if a really serviceable developing tent were introduced it would sell like wildfire. It has been the one thing wanting for several seasons past. To begin with, I have little or no fault to find with the outside dimensions of the present tent; writing from memory, a 10×8 is about 28 inches by 21 by 7—nothing out of the way. The shape is in its favour—which is more than can be said of other types, such as the umbrella, the music-book pattern, and so on. For the wooden body, however, I would substitute something else; wood is not a vital necessity, it is heavy and untrustworthy. I think a well-made mail canvas would do. It is largely used for camera cases, is strong, and if not absolutely light-tight might easily be made so by being given an inner lining of ruby fabric. It will stand a tremendous amount of wear. I have seen camera cases which have been all over India and Europe, braving a thousand vicissitudes and returning quite uninjured. If it were employed for the body of the tent it would do away with a power of weight, and, what is more, as it is of such an eminently serviceable nature, would obviate the employment of costly brass-bound mahogany for tropical climates, and indeed of a travelling cover which, with wooden bodies, is a *sine quâ non*. Then, as to the stand. This is, as most people are aware, an imposing affair; it is twice the size and weight necessary, although I am bound to admit it has to support a lot, and is both rigid and strong. But under our reformed tent it need not be so big, and strength can be obtained with less work. I would make the head into which this tripod fits a permanent part of the base of the tent. The major portion of the front elevation of the tent ought to be monopolised by the window—the little strip of glass which makers give us at present being ridiculously inadequate, especially if the outside light be dull. There ought to be no difficulty on this head, for, of course, when the tent was closed the glass would, as now, be shielded from breakage by a movable panel or door.

One of the principal causes of the unpopularity of the present dark tent is that although it is fairly easy to set up it requires considerable ingenuity in order to close it again. A vast cloud of twill, supported by a framework of iron rods, seems necessary to ensure immunity from the actinic rays. One would think that two thicknesses of some suitable material could be used; apparently, however, this is not the case, for three and sometimes four thicknesses are considered necessary. This covering seems to be too voluminous—and as a matter of fact it is, for manipulative purposes. I should think a fairly stiff canvas lined with ruby fabric and bellowsed, so that it can be easily folded and unfolded when packing and unpacking, would be more satisfactory than the present arrangement. As it is, when packing up the tent a neat fold is almost impossible at the hands of an ordinary male brute, feminine assistance never being at hand when it is wanted. An inverted conical bellows—so that the lower part could be easily secured to the body—would be a great blessing, and is highly practicable. Naturally there would be no absolute necessity for bellowsing the covering that formed the roof and sides although, properly done, it would be an advantage.

So much for the carcase of our model tent. I should say that the weight of one constructed upon my suggestions would not be an ounce more than seventeen pounds, and would come very near to something like real portability. The employment of such a material as mail canvas—or something similar—as a substitute for wood is highly

* Concluded from page 134.

desirable. Intending purchasers of the present form of dark tents are invariably flooded by their weight, their general stuffiness, and that indescribable ponderousness always, in my mind, associated with them. It is no uncommon thing for a cultivated amateur to exclaim, "I could make a better one myself." That is just the very thing that is wanted, and if somebody would only attempt it, and publish the result of his labours, much might come of the attempt. "Oh, but we are quite in the hands of the shopkeepers!" cry some. *Au contraire*, Messieurs, they are in yours. The coming season looms in sight; I believe that if a developing tent modelled upon the imperfect suggestions I have thrown out were placed on the market it would find a swift sale, particularly if its internal arrangements were correspondingly improved. This, by the way, reminds me that I have not, as yet, touched upon that branch of the subject, which must perforce stand over for a future opportunity, when, perhaps, we will "step inside."

MARSTON MOORE.

METHODS OF RETOUCHING.

III.

My own experience of retouching began in Paris very many more years ago than I care to set down on paper, still I do not wish to lay down my own system, or systems, as infallible, or the ones fittest for imitation. I therefore wish to be as general as possible, and give for instruction the methods producing results which I consider the most correct as well as artistic. For this purpose, therefore, I wish to make a few remarks upon the methods of retouching in Germany, France, and the Continent generally.

I will take Germany first, as the methods most practised there are bold and decidedly artistic. Even when they fail as *negative retouching*, which to be really good must preserve likeness, they possess a certain independent merit of their own, owing to their decided and skilful treatment. A good German retoucher treats a head, say, the ordinary vignette cabinet size, just as he would a crayon drawing of similar dimensions. This, needless to say, is a bold treatment for a negative, and one likely to efface the leading markings in a finely lighted negative. Still, I have seen some very beautiful results produced, but the retoucher must be very skilful, or he will have to pay for the beauty of effect by the comparative loss of resemblance.

He generally begins by carefully filling up all the transparent spots or lines, as in the methods already described. He does this, however, in a slightly different manner to those I refer to, inasmuch as he uses the point of the pencil much more, lightly dotting or spotting until he removes all the markings—such as blotches, freckles, and optical exaggerations—until the face presents, comparatively, a smooth and even surface, free from any traces of such blemishes.

He now starts on the modelling of the face, which he accomplishes by means of cross hatching as a foundation, placing a line or touch here and there as his eye may catch a defective or unfinished portion of the face showing a want of gradation.

The next points treated are the *high lights*, which he at once puts in their respective places, and then gradually softens into the half tones and shadows, until the negative assumes that appearance of rotundity and delicacy of modulation so grateful to the eye of a retoucher. To produce this effect is the sole object he has in view at starting, and its consummation not only affords him pleasure, but is a kind of reward for his pains and skill.

As a retoucher following this school becomes more and more experienced, so his touches or strokes of the pencil will become bolder and bolder, under which latter treatment a negative will possess much greater artistic value, inasmuch as it will be freed from that mechanical stiffness so generally observable in a beginner's work. As is natural to suppose, broad and bold cross hatching, even in skilful hands, will not always secure a finished picture, so our retoucher of the German school begins to fill in any defects which may appear between the lines or cross hatches. In this way not only a bold and dashing effect is gained, but also a very taking picture will result. Notwithstanding all that can be said in favour of this method, it always will have its glaring disadvantages as regards portraiture generally. For what is termed *publication pictures*, it is undoubtedly good, as a brilliant result is certain to be obtained, and the loss of likeness is scarcely a disadvantage. In pictures of this class the resemblance is a matter of very secondary consideration. The public will not buy an *ugly* portrait, especially when it is of some one they do not personally know; but they do buy a "pretty picture," and make themselves believe it is also a correct likeness. Whether the public be right or wrong in this regard I will not dare to offer an opinion. I will only say with the old showman, "They pay their money and they have their choice."

The method practised most generally by the French has at least

one very great advantage over their German rivals, inasmuch as the likeness is much less likely to be lost, this, too, although there is but a trifling difference in the handling. Indeed, in most of these methods, the commencement is nearly the same, that is to say, the retoucher begins by levelling up or spotting out all the defects on the negative until it becomes even throughout, and then worked until it presents a sufficiently soft appearance. When they have worked a negative to this stage (having levelled the face and removed all the inequalities) the majority of good French retouchers effect the necessary modelling by making very fine, long, downward strokes, somewhat curved. This treatment will not produce the effect of that stipple which would be the most suitable, but it will make the face so treated very smooth and soft.

This method, too, is not so vigorous as the German, but, as you may easily see on consideration, the likeness is less likely to be lost. I must say I prefer it to the other, because a somewhat similar result can be gained without losing what to me seems the most essential quality of a portrait—the likeness. It is also quite as acceptable in fancy work, or what may be styled "*publication work*," as its rival.

Before the "dry" plates became generally in use, the old-fashioned collodion plates required the help of a medium in order to give a *tooth* to the film. Generally the negatives were treated with a solution of gum, or a mixture of gum and dextrine, dissolved in warm water. This washed over the film of a negative would give it a surface as readily worked upon with a pencil as a sheet of drawing paper. Like everything else in life it has its disadvantages, the worst being the liability of the film to split when varnishing. This misfortune is of course accounted for by the absorption of moisture by the gum and dextrine. The Germans, in order to avoid this trouble, mostly retouched on the *varnish*, using a medium such as already described to obtain the necessary *tooth* for working. So much for old style.

In the modern "dry plate" this danger of the films splitting is altogether obviated, and each artist can follow out his especial style to his heart's content. We have only to use a medium, of which there are numbers in the market, to give the necessary surface for taking the pencil, and then dash away in pursuit of the desired result. We have unfortunately at times to put up with a very great trouble, notwithstanding all our advancement. There are various kinds of mediums which, although giving a splendid *tooth* for working on, fail to retain the work placed upon it during the process of varnishing. Necessarily this entails double work upon the retoucher and is nothing short of a misfortune to the poor, hard worked, and (I don't hesitate to say it) generally underpaid retoucher who works "on piece."

The coming off of the work during varnishing may result from a number of causes. If the film be slightly damp, the plate not properly heated, or the varnish not of a proper consistency, all will result in worry and trouble for the retoucher. Still, like all who worship, however humbly, at the shrine of art, we must take "the rough with the smooth." I may here tell all intending retouchers that they will find much more of the former than the latter as they struggle along. They will also find some difficulty in finding a medium that will make it more *toothsome*, and even varnishing will not make it smooth.

There are some very fine specimens of work come from Russia, notably St. Petersburg and Moscow. I cannot positively say how they have been retouched, but judging from the subjects before me I feel inclined to say the German school, but in a modified form, predominates. Vienna, too, sends us some fine specimens of the photographic art. The retouching in my opinion, although very fine and pretty, bears the stamp of being over laboured. As I said before, excessive work or too bold and dashing a style, may be all very well for fancy pictures, but they are simply absurd when employed in portraiture. I would not dwell so much on this point only my object has been in these "papers" to treat retouching almost solely in its connection with portraiture; and good portraiture without likeness is to me an impossibility.

Taking a look all around, I think America has sent us as fine specimens of photography and retouching as any country in the world. In the *first-class* American photographs, as compared with similar works produced on the Continent, I think there will be less fault to be found. They do not look so over worked and hard. Even in cases where we, as experts, know they have been so treated, it will not be observable to the eye of the ordinary observer. The climate of England generally is not over favourable to the production of really excellent photography. Still there are times when it is *favourable*, and the results gained on such occasions will, I am confident, hold their own beside the best produced in any other country in the world.

A few remarks on the treatment of so-called "Rembrandt" pictures may not be amiss just here, as I think it will nearly complete our

study of retouching and its methods as strictly applicable to portraiture. In many cases this kind of picture will be found somewhat more difficult to manage than the generality of ordinarily lighted ones. Many times photographers attempting this style of lighting either make the light upon the profile too strong or the shadow too intense. To the retoucher one fault is as troublesome as the other. Negatives which would yield very decent results are often spoiled by after intensification, and thereby effacing all the details in the light side of the face.

There is no light in nature however strong but has detail and modulation, and so also should it have in a negative. Rembrandts are mostly profile, so we would start work at the edge of the light upon the forehead, and soften it into surrounding parts until the temporal arch is reached; in this case the drawing of the arch should be preserved by the placing of a light to show its formation, but always keeping same in harmony with the prevailing shadows and half tones. Great attention should be paid not to efface the modelling, but rather to preserve the relative importance of each detail. There is no indication of the malar bone and the palpebral muscels which should be lost. I do not mean unduly accentuated, but sufficiently relieved so that they will show well when printed to that density necessary to show off this style of picture to the greatest advantage. There never can be a good Rembrandt picture which will not print with clear, brilliant shadows.

The light on the nose must be carefully worked, and the drawing of the same rectified if necessary, also the corner of the eye, and the ofttimes deep shadow formed by the orbital arch. In under exposed negatives the retoucher will have a deal of trouble treating these latter points. The lights on the cheek bone (giving formation to the face), the lips, and chin, are all points which demand careful attention. Where the negatives are defective owing to under exposure, the work necessary, both before and after varnishing, can be supplemented by matt varnishing and stumping on the reverse side. This latter must only be resorted to after the ordinary work has been carried as far as possible.

Should there be little or no variety in the tone of the background, a pleasing effect may be produced by indicating a light close to the figure or face on one side (generally the one remotest from the light) and somewhat more distant from it on the other. Before attempting this, examine any portrait, so lighted, painted by a good artist, and found your own work on the same principle.

REDMOND BARNETT.

LANTERN ARRANGEMENTS AT DUNDEE.

In connection with Mr. G. D. Macdougall's remarks on the splendid success that followed the efforts of the Dundee Photographic Association to utilise the electric light for lantern work, I may perhaps be allowed to say a few words. I was at once an interested and a disinterested party. As Mr. York's slides from my negatives were the ones used, and as I was the lecturer, I may safely be said to have had an interest in the affair; but as I am not a member of the Dundee Association, and had no hand in the lantern business on the occasion in question, I may claim to have had no prejudice for or against the system of illumination. But this I will say, that not only were my previous doubts as to the electric light for the lantern completely dispelled, but in all probability I shall for many a year to come look upon the arrangements of that evening as my *beau idéal* of what such an entertainment on a larger scale ought to be. I have of late years acquired some slight experience of the routine of limelight lantern work and lecturing, and I do not believe that any reader of this JOURNAL will put down to egotistic motives my action in commemorating to a certain extent the events of February 10 in the Kinnaird Hall of "Bonnie Dundee."

I was most politely, but unnecessarily, consulted before the meeting as to the light for the lantern and as to the size of the screen. When I heard of a thirty-foot disc I was, I admit, adverse to the idea. My "adversity" was only slightly modified when I heard that the screen was to be whitewashed; it was modified to the extent of about twenty or twenty-five per cent.; for at a guess, and judging at hazard, I calculated the waste of light by absorption of an ordinary screen to be about twenty per cent. I was not able to form any opinion as to whether a screen of such a size would be either necessary or advisable, for I did not know the size nor the shape of the hall. I thought, and I still think, that a twenty-five feet screen is large enough for most halls, and, if anything, a shade too large for the best slides and limelight. But I am now convinced that the thirty feet screen was not a bit too large for the hall, and not a bit beyond the power of the light that was used on the occasion. While I was on the platform I could form no opinion as to the sharpness of the detail, the quality of the illumination, nor the proportions of the screen, all that

I could verify was the remarkable steadiness of the light. But after the opera was over the electricians kindly "turned on" a slide, while I viewed the effect from the body of the hall, and I could not but own that for brilliance and just proportion nothing better could have been desired. The screen was tastefully draped with red cloth, and was altogether a paragon of screens.

I had several times before seen the electric light used as the radiant for optical lanterns, and if I doubled the wisdom of a thirty-foot screen I still more questioned the advisability of using the electric light. I never before saw it anything like steady, and I never before liked the colour produced by it shining through any slide: in fact, I had mentally condemned the electric light for the optical lantern; or, to put it at the mildest, I could only "damn it with faint praise." I do not know what particular form of lamp was used at Dundee, nor did I see the machinery which was across the street, but I am able to attest the steadiness and good colour of the light. It is a pity Mr. Macdougall has not told us more about the lamp; perhaps he may be induced to do so still. The light was so brilliant that even with coloured glasses I could not examine it—(to say the exact truth, nobody would have been much the wiser if I had been able to examine it).

One thing must not be omitted in this connection. The heat of the lantern was astonishing. The slides required to be made quite hot on a gas stove before insertion in the lantern, otherwise a smash would have been inevitable, and the vicinity of the lantern would be a good preparation for Carpentaria.

No signalling was heard between myself and the lanternists, for right under my nose was an electric "push," which acted on a bell in the lantern room, the bell being muffled so as to be inaudible to all but the operator. The scenes were changed as if by the mere exercise of my volition, or as if I had trained them to come on spontaneously in their proper places.

Altogether, I shall not in a hurry forget Dundee; and perhaps I may be allowed to add a few words to what I have written, by way of making a few remarks on what I saw during my memorable and delightful visit to that city. I shall avoid remarks that I might be tempted to make regarding the social kindness I received, and I will endeavour to confine myself to what will interest my readers.

I saw and used the studio of an amateur, a studio which, for convenience and elegance, is not surpassed by any studio I ever saw. When I say that 15×12 portrait cameras, with stands and lenses to match, were rife in the studio, and when I add that I found Seavey backgrounds on Morgan's supports, it will be understood that all the necessities for good work were available, the brains and taste being presupposed. I admit it was a new and delicious sensation to me to fire off a 12×8 plate, under expose it, and still escape without an anathema. I did it, however, several times, and the owner of the plates—if he did not like it, at least pretended not to object. And I actually discovered a person—not an old maid—who really did not like being photographed. It was worth while to go to Dundee for that alone! The owner of this studio and I spent some time testing various lenses, and I found among other things that I possessed a fifteen-inch single lens, that gave me straight architectural lines to within an inch of the edges of a 12×8 plate. If there is any distortion it is not visible to my eyes. I believe there is much misunderstanding about the capabilities of "single" lenses; every day I am coming nearer and nearer to the use of single lenses alone, even for subjects supposed not to be amenable to any but rectilinear.

I also visited the establishment of Mr. Valentine, the widely known photographer, chiefly of landscape. This gentleman claims to have the largest establishment of the kind in the world, and he is at present making a great addition to it. The boss of this show may safely lean all his weight on his staff, but he seems to prefer to lean chiefly on himself. He develops himself all the negatives sent in by all the operators he has travelling about, and as these amount to thousands yearly he ought to know something about development. I noticed that he used in his dark room a ruby globe open at the top, the room being all painted red, so that I found at least one man of like opinion with myself as to the best colour for a dark room. The system of saving residues of silver appeared to me very complete, and I saw in use enormous print washers à la Sturrock, only "far more so." Mr. Valentine prints to a large extent and with great success in platinum-type, and a gentleman of the staff, who I think was called Frank, very frankly showed me how he did it. The whole detail of printing was being carried on on a scale to me positively alarming, and I left the place in a very thoughtful frame. I saw a very great many young ladies—all unmasked and untouched, some round, some oval, some cushion-shaped, but all, I am sure, quite square; to any one I might (on the 14th) have said, "Thou shalt be my Valentine."

A very good tone prevailed over the whole establishment, every one seemed to be fixed and permanent; H. S. would have fled in despair

and in fact the whole arrangements showed the most careful development. Though the establishment is being enlarged it would be very difficult to reproduce it even with a very heavy layer of gold. Mr. Valentine affects negatives of a very plucky nature; he says that he considers albumen prints from such negatives to be more lasting than those from more delicate *clichés*, and I agree with him down to the ground. Plucky prints seem to take on more gold, which appears to me the best safeguard for permanence in albumen printing. Mr. Valentine had all his negatives—considerably over seven in number—arranged in racks or grooves, and so numbered that the printers can, without racking their memory in the *press* of business, pick out any required negative at a moment's notice. Each negative requiring a cloud printed in had its particular cloud negative, and a certain number of young ladies—not “Celestials”—were employed in the “sky line” alone. These young ladies were plainly visible above the horizon, and may be said to have reached the highest point or zenith of the profession. Some (of the ladies) had a fine sharp outline, while others were beautifully vignettied away. I have, however, said enough on this subject, and must now dissolve into another. Mr. Valentine turns out an enormous number of slides: for this work he finds winter the season best suited; during frost he makes his slides, and the thaw is appropriate for his process, which is the wet one.

ANDREW PRINGLE.

FORMULÆ FOR DEVELOPERS: HOW SHOULD THEY READ?

[A Communication to the Society of Amateur Photographers of New York.]

I THINK that the questions we have for discussion to-night are both apt and timely, especially so when we see how flooded the literature of our art-science is with the constantly increasing armies of developers.

The tyro is early told by the many writers “to choose out a good developer and stick to it.” Sound and good advice, surely. But how is he to pick it out?

It is like taking a young man into a machine-shop and saying to him, here are all the materials required, and all the tools necessary to work with, now go to work and build a locomotive. Does he know the difference between a wrench and a jack screw? So it is with the beginner; scores of formulæ for developers are before him, but what does he know of the properties of the different ingredients? The pyro, what is it for, and how does it act upon the emulsion or the plate to bring out the latent image? The carbonates of soda and potash? He sees that some use one, some the other, and some both. Is he told their action and the requisite amount necessary to produce that action, and what is the sulphite of soda added for to the above, sometimes in “A” and sometimes in “B”? He is told that citric acid and its salts and the bromides are restrainers. Restrainers of what? He sees that the bromides are recommended for over-exposed and under-exposed plates; but why? And so on. Even the fixing bath is a perplexity to the beginner.

But even when he has mastered, to a considerable extent, the properties of the different articles comprising the developing bath, his troubles are not at an end. The great array of unscientific, incongruous, bulky, wasteful, and happy-go-lucky developers (and a careful survey of the different published formulæ will soon show that each of the above classes have one or more in its ranks) stare him in the face. From which is he to choose? If he is determined to know himself, and not take the word of another, he begins by mixing up one developer after another according to the formula given in each case, and tries them in turn, in search of a good developer and the one that will give him the best reward for his work; but he soon finds the shelves of his dark room full of bottles and his pocket-book empty. Or suppose that a fair young lady amateur, not having the knowledge, time, or facilities to prosecute the above experiments, chooses, by the advice of a friend, a certain developer, which must be made up strictly in accordance with the formula. Intending to take a trip for a short stay in the country where she hopes to make some shots at choice bits of woodland and lawn, she has the developer made up for her at the nearest drug store, never dreaming of the result in bulk. Now “A” calls for sixty ounces, “B” forty-six ounces, and an equal quantity of hypo solution is required. To start she must sling her camera in its case over one shoulder, tuck the tripod under her arm, seize two one-gallon demijohns in one hand, a demijohn of the same size and one or two hand-bags in the other. Her dismay at this bulk can easily be seen. “The impediment” of this outfit would soon tire out the most enthusiastic of amateurs.

How much better it would be, especially to the amateur, if all the formulæ were given so many grains to the ounce of water. It would take but a glance to convince him whether it was a scientific one or not, whether the proportions of its ingredients were correct and

capable of producing the best and desired results. What a saving of time and money it would result in; saving in solution of many of the salts used, and, especially sulphite of soda, which rapidly deteriorates and becomes useless, or nearly so. Why then make them in that way? Why not let the formula read:

Carbonate of soda.....	So many grains.
Sulphite of soda	“ “
Pyro	“ “
Water	1 ounce.
Carbonate of potash or soda	So many grains.
Water	1 ounce.

And then multiply each ingredient by ten or its multiple, and you will have a developer of sufficient quantity and sufficiently fresh to meet all demands; and then, if the plate makers would paste on the cover of their boxes their formula for the developer reduced to grains to the ounce, it would be of great advantage and economy to any one trying one or two plates. The developer could be made up before opening the boxes.

A careful analysis of eighteen published formulæ shows a great diversity in the amounts of the ingredients, and

The largest amount of pyro used to the ounce of water..	10	grains.
“ “ sulphite of soda “ “	80	“
“ “ carbonate of soda “ “	40	“
“ “ “ of potash “ “	21 $\frac{1}{2}$	“
The smallest amount of pyro used to “ “	1 $\frac{3}{4}$	“
“ “ sulphite of soda “ “	5	“
“ “ carbonate of soda “ “	1 $\frac{1}{2}$	“
“ “ “ of potash “ “	5	“

In many of the formulæ the amount of sulphite of soda was largely in excess to the quantity generally conceded to be required in proportion to the pyro—four of sulphite of soda to one pyro. But in one we have sulphite of soda, fifty grains; pyro, six grains. Another formula says his alkali is weak, forty grains to the ounce of water!

The use of saturated solutions in making up the developer should, I think, be discarded, for the reason that they are uncertain, the changes of temperature and evaporation rapidly affecting them; and then the mixing of two or more saturated solutions oftentimes produce the deposition of more or less of one or both of the salts, but never in equal proportions.

I think also that the use of either the dry or granulated salts is also objectionable, especially the carbonates—carbonic acid is not the most stable element. In the crystal you have a fixed and determinate quantity, and they should therefore always be called for.

I have not referred to the part of the question whether the ounce should always be regarded as composed of 480 grains, for if the method of writing the formula in so many grains to the ounce of water be adopted, there is no further trouble to be apprehended as to whether the ounce is 437 or 480 grains. But should the term be used? I think that the quantity in grains should be given (in 437 $\frac{1}{2}$ grains or 480 grains). This is rendered necessary from the fact that most of the articles used are sold by avoirdupois weight, 437 $\frac{1}{2}$ grains. Another good plan would be, in directions for making up the formula if the grain system is not adopted, to say: Water, to make so many ounces. One should recollect in reading the English formulæ that there is a difference of four ounces more in the pint used by them.

JOHN H. JANEWAY.

FILM PHOTOGRAPHY.

[A Communication to the Bristol and West of England Amateur Photographic Association.]

IN THE BRITISH JOURNAL PHOTOGRAPHIC ALMANAC for the current year will be found a contribution of mine on *Stripping Films*; but since it was written the process in question has been so improved that I gladly take this opportunity of bringing it before your notice, and at the same time of supplementing my paper in the ALMANAC. The Eastman Company were kind enough to let me have for trial some of the first of these films which came over from the States, and I worked them last summer with complete satisfaction and success—so much so that I have no hesitation in recommending the process as one that will produce negatives in all ways equal to glass, and in some respects superior.

If I may not be considered out of place in going over the same ground twice, I may describe the stripping film (“American Film” the Eastman Company call it) as a film of *insoluble* gelatine emulsion attached to a sheet of paper (which serves as a temporary support) by a thick layer of soluble gelatine. In appearance it resembles the ordinary negative paper, and its treatment is the same as regards exposure and development; in fact, if the negative is consid red not

worth stripping it can be squeegeed to glass and printed from in the regular way. Presuming the emulsion-coated paper to have been exposed in the roller slide (and this is the only way to work films properly), it is cut into the right lengths and then developed. I may here remark that the emulsion is very rapid, clean, and free from fog, giving a brilliant image with any amount of density that may be required.

As to development, the Eastman Company, in their original instructions (they have not yet issued the new directions) lay especial stress on the fact that soda developer must be used, as there is a risk of the pyrogallie acid, when mixed with ammonia, attacking the gelatine substratum and rendering it insoluble. Although this may be right in theory, it is not so in practice, and I have always used ammonio-pyro development in preference, as giving negatives of better printing colour.

The following is the formula:—

- A. Sulpho-pyrogallol.
 B.

Potassium bromide	120 grains.
Ammonia ('880)	6 drachms.
Water (distilled)	6 "

To develop—take water, 2 ounces; A, 20 minims; and B, 2 minims, commencing with half the quantity of B.

After development wash the negative well and fix in tolerably clean hypo; this will, as a rule, do away with the necessity of using the acid and alum clearing solution later on. The negatives only require a few minutes' washing and are ready for the first of the stripping manipulations, namely, *squeegeeing to the collodionised glass*. Take a clean glass plate a quarter of an inch larger all round than the negative, dust it over with French chalk, rub clean with a cloth, and then coat with plain collodion. I am informed that enamel collodion diluted with two ounces of ether and one ounce of alcohol to the pint is the correct thing, but I turned out an old bottle of autotype transfer collodion, which answers perfectly. Let your collodion *set well*, and wash the plate thoroughly until the greasy lines have disappeared, then put your negative face downwards into the dish, bring it out clinging to the collodionised plate, and squeegee in the usual way, of course, putting a sheet of American cloth between the negative and the squeegee, and not using the latter too vigorously. Now lay the plate on a table, negative upwards, place two thicknesses of blotting-paper over it, and then put upon the top of it a board with almost ten to fourteen pounds weight on it. Take negative No. 2, squeegee it to a collodion-coated plate as before, and place it on the top of No. 1 with two more sheets of blotting-paper, and so on until you have a pile of about a dozen negatives under the board. This is an operation that does not take long, as a dozen plates can be coated and the negatives squeegeed on within an hour, and by this time they are ready for the first stripping, which may take place any time within fifteen minutes to two hours (or more) after the squeegeeing.

The *stripping off the paper support* is next proceeded with as follows:—Turn your pile of plates upside down, and place No. 1 in a porcelain dish, pour over it water at 100° to 120° Fahr. (not hotter). In about two minutes the paper will blister up and become loose at the edges, then you can lift it up bodily at one corner, and gently draw it off the negative film, which will remain firmly attached to the glass; then, with a little more warm water, wash off any of the gelatine substratum that may be still sticking to the film. With ordinary care failure is impossible; but it is well not to use water at too high a temperature, or to attempt the stripping too soon after squeegeeing, or failure may result in either case. Stripping from the collodionised plate contrasts wonderfully with the original method, which required great care and delicacy of manipulation, for you can go ahead now without the slightest risk of spoiling your negative. No pouring boiling water over the film or rubbing it with the finger (generally into a hole) to get off the paper which would stick in some obstinate place, and what is equally important, no waiting for the negative to dry between the squeegeeing and the stripping, but you can develop, strip, intensify (if necessary), and attach the gelatine skin, all one after another without delay. As regards intensifying, you can judge of the density of the image so well in developing that it should be seldom necessary, but when it is required, silver or mercury intensification can be applied at this stage. Should clearing be thought desirable, acid and alum can be used, but *not previous to the stripping*, since alum in any form would probably render the gelatine substratum insoluble.

To *Squeegee the "Skin" to the Film*.—When the process was first introduced in America a warm solution of gelatine was poured over the film after the paper had been stripped off, and the plate was then set on a level shelf to dry; but as this involved a lot of trouble in the drying—which took longer than a gelatine plate does to dry in its preparation—the Eastman Company substituted what they term a

"skin," which is squeegeed to the plate instead. The "skin" is composed of gelatine, to which is added glycerine to render it flexible, and must be cut in pieces rather smaller than the negative, as it expands considerably when wetted. It should be soaked in water containing a little glycerine (glycerine, one ounce; water, twenty to twenty-five ounces), for if placed in water alone the glycerine in the skin dialyses out, and the film becomes horny on drying. If, on the other hand, too much glycerine is used the film will take a long time to dry, and be difficult to strip from the glass. The solution is best used fresh for each lot of films, or difficulties will occur in the drying. After the "skin" is soaked until quite limp it is squeegeed on to the film—bright side outwards—taking care to avoid air bubbles; it is then set to dry, the time occupied in drying depending very much on the warmth of the room and the state of the atmosphere. I have repeated at length, from the article in the ALMANAC already referred to, these details bearing on the treatment of the gelatine "skin," since I consider them important for the successful working of the process. As to the drying of the plates, this occupies about the same time as the ordinary gelatine negatives on glass. I usually carry my films into the kitchen at night, and find them dry next morning. When perfectly dry the film should be coated with collodion, and in a short time can be cut round the edges with a sharp knife, and stripped without difficulty from the glass. The object of this last coating of collodion is to prevent the film being affected by damp, and in this respect these latter negatives are superior to those made by the old method, which were liable in time to become slightly spotty, or to get stained by contact with the sensitised paper in printing, if the paper was not absolutely dry.

Owing to the recent improvements in the process it will be found: First, that the stripping off the paper support is now a most easy and certain operation, on account of the drying of the film after squeegeeing to the plate being dispensed with; and, secondly, that the whole of the manipulations will occupy no more time than is required for the washing and drying of a gelatine negative.

Several films should be treated in succession; and of course a certain amount of method is necessary in working a process of this nature, but nothing beyond ordinary care is requisite to make it a success. Personally, I have found it in every way successful, and consider the negatives made by it will compare favourably with those made on glass, and be superior as regards halation—in fact, I look to film photography for a distinct advance in the future in both landscape and interior work.

For tourist work, some films are simply invaluable; and who has not felt the want of them when travelling abroad, with the difficulties of the Custom House, the bulky luggage, and the risk of breakage. But we shall change all this, and with our roll holder and spools of "strippers," set off in future to the "Continong" with the happy assurance that we have no plates to be smashed by the railway officials, or to be opened at the *Douane*; and added to this, shall have the satisfaction of knowing that at the end of a long day's toil we shall be freed from that most tiresome of occupations, the changing and numbering of one's plates. Eastman and Walker, we shall bless you then!

H. MANFIELD.

THE LANTERN MICROSCOPE.

[Abstract of a Communication to the Manchester Microscopical Society.]

It is some eight or ten years since I felt dissatisfied with the results which I was then able to obtain with the ordinary lantern arrangements for projecting microscopic objects upon the screen, and began to make experiments with the aim of getting more successful illumination. The amount of light transmitted through the bi-lens lantern condenser being in the inverse ratio of the square of the distance between it and the luminant, I tried to shorten the space by the well-known device, first introduced by the Rev. W. T. Kingsley about 1855, of adding a third lens to the other two, and thus shortening the compound focus. But this I soon found was, without further addition, of no use whatever, as the cone of rays at its apex was so large, or the light passed through it at so great an angle, that it was impossible to transmit it through both the object and the objective. Thus the beam of light, however strong it might be at the focus of the condenser, did not reach the screen, and therefore served no purpose except that of boiling the object in the balsam used in mounting it.

I next placed another lens in the cone of rays a little beyond the focus, and hoped by this means to so lessen its diameter as to make it capable of transmission. This was a sort of sub-stage arrangement, and was found to be a great improvement when the lens was of the right focus for the objective, and was situated at the right distance from both it and the object. To be able to thus place it at the right distance from both, meant having a sub-stage lens for all objectives

differing widely in power, the focus of each being such as the power and construction of the others might require. Rack and pinion movement was also found to be necessary, so that the rays might be properly focused on either side of the object. The lenses used should be large enough to take in the whole cone of the principal condenser, and for the higher powers it is requisite to combine two or three of them together. The highest as well as the lowest powers may thus be made useful for lantern projections. Mr. Kingsley stated in his paper upon this subject at the time I have just named that he could transmit as much light through the higher as through any of the lower powers, and gave diagrams of the arrangement which he made use of.

So much for the past; now we come to the present. The objectives which I shall use this evening are 2", 1", and $\frac{1}{10}$ ". The 2" requires the sub-stage lens to be a little over 2" focus, $1\frac{3}{4}$ " diameter, plano-convex. A similar kind of lens, $1\frac{3}{4}$ " focus, proves in my hands to be a good all-round condenser for all powers from $\frac{1}{2}$ " up to $\frac{1}{10}$ " objectives. By liberal use of the rack and pinion and of the concave lens to be presently described, this sub-stage lens gives the most brilliant results throughout this wide range of powers. The $\frac{1}{4}$ " objective, when it is desirable to use it for photographic purposes, requires two lenses; the back one to be $2\frac{3}{4}$ " focus and $1\frac{3}{4}$ " diameter, and the front one $1\frac{1}{4}$ " focus and 1" diameter, both plano-convex. This also makes a good condenser for the $\frac{1}{10}$ " objective. All the lenses must have the curved surfaces turned towards the lantern. The luminant goes to within $1\frac{3}{4}$ " of the back lens of the principal condenser with the 2", and to within 2" with the other two objectives. I have tried it closer than this, by using a back lens of shorter focus without advantage, in fact, considerably otherwise. If a flint concave lens is placed in the cone of rays about one or two inches before the really active ones begin to cross, the light is much improved. The concave which I use is about 6" focus and $1\frac{3}{4}$ " diameter. It is so placed in the tube which carries the other sub-stage lenses that its distance from the principal condenser can be altered so as to modify the length of the cone of rays to adapt the focus of the other lenses to the objective when they do not exactly meet its requirements. The concave lens was, I believe, first introduced into the lantern cone of rays by J. T. Taylor in 1866, for the purpose of parallelising them, but I do not use it for any such purpose in this lantern microscope. In my lantern polariscope I imitate Taylor in the use of the concave, but here the purpose served is quite a different one. My lantern condenser is $3\frac{3}{4}$ " diameter, with a plano-convex $3\frac{1}{2}$ " diameter and 7" focus, mounted upon the back of the tube which carries the other lenses.

In lantern microscope projection three things are essential. The first is brilliant illumination, the second large amplification, and the third clear display of detail. But brilliant illumination does not mean a dazzling display of light upon a large white screen, showing a dark, patchy outline of an object, without detail. Objects shown in this way are far inferior to an enlarged woodcut. The light must be made to enter the object so as to bring its structure out to the eye of the onlooker. But no amount of light will do this if its dimensions are too small for the crystalline lens to form an image of it upon the retina. With high-power objectives the light must, in the nature of things, be greatly subdued. Still, a large image, moderately but properly lighted, can be far better seen than a small one many times as bright. An object may in fact be too bright to be seen. If rays of great angle are too powerfully converged upon it the image becomes as bright as that part of the screen which represents nothing but bare glass. It is in this case just like an over-exposed photograph, flat and without contrast. The image may, therefore, be too bright for the screen, just as it may be too black for it, and what we have to aim at is that mean which will show the detail in one without making the other too glaring.

Having made our arrangements according to what is here advanced, we ought to be able to show the various minute organs of insects and the details of vegetable and animal tissue. I have shown very finely the blowfly's tongue over sixteen feet long, and the male flea with its outstretched legs twelve feet long. Sections of spine of echinus may be magnified to seven or twelve feet diameter, and section of a rat's tail eight feet diameter. Mites in cheese with such powers become large as guinea pigs, and *volvex globator* gracefully rolling over a sixteen-foot screen are larger than tennis balls. The cornea of the *dytiscus* is a most wonderful object when shown eight to ten feet in diameter.

When I say that such things can be shown in such enormous sizes, you must not suppose that the display will be like an outline map, black and skeleton-like in appearance upon a white ground. Instead of that the small capillary bloodvessels in anatomical sections, the various appendages of the feet of insects, the hairs of plants, the rings of insect trachea, the eyes of insects with the light gleaming through

each facet of the cornea, with other equally minute details, can be displayed to an audience with very great satisfaction. That you must admit far surpasses anything ever achieved by the old lantern microscope, and we boldly challenge any admirer of the old method to show that he is not now left as far behind by the new one as the old stage-coach is left behind by the railway train.

I think I ought to say that my lantern microscope has been made by myself. All its details have been worked out by myself. I have, of course, utilised any old photographic lens mount, or old microscope fittings which I could get to work up into my arrangement, so as to save mechanical labour. It fits, as you will see, into the ordinary lantern front. The alum trough goes into the place which holds the slider when the lantern is used for ordinary pictures. The stage is one of Dancer's old lantern microscope stages, but is modified so as to hold and enable me to change the sub-stage condensers, which can be done more easily and with less loss of time through mine than it can be done through any other arrangement. The compactness of the instrument is also something worth considering.

Since the foregoing pages were written I have fitted up a one-inch objective which is very satisfactory. It transmits a large beam of light, and gives a flat field of great size, the central and marginal definition being fairly good at the same time. As a rule the best ordinary objectives give no definition beyond a small circle in the middle of the field.

NOTE.—This lantern microscope was exhibited at the Manchester Microscopical *soirée* on the 29th January, 1887, attached to a photographic camera, the bellows body of which opened out to thirty-six inches. With the $\frac{1}{10}$ " objective, images were shown upon the screen magnified eighty diameters, and were seen well defined, brilliantly and equally lighted, without covering being placed over the camera, notwithstanding the gaslights overhead and all round the room. The field was noted for being as even as a sheet of writing-paper. When the lantern door was opened much astonishment was expressed when it was seen that all this illumination was obtained from a small paraffine lamp burning with a single half-inch wick. Thus the lantern microscope in this form becomes as useful to the micro-photographer as it is to the lecturer or the science teacher. W. LEACH.

Our Editorial Table.

INSTANTANEOUS PHOTOGRAPHY.

By C. W.

Bath: Charles Seers, 1, Argyle-street.

THIS is the maiden effort at photographic literature by a gentleman whom we well know to be capable of writing with authority on the subject on which he now treats, in what is little more than a pamphlet of eighteen pages, but in which there is much that is useful. The author favours the production of small negatives, and believes that the near future of photography lies in the direction of "very carefully taken, artistic small negatives, with the view to these being either in part or in whole subsequently enlarged."

The term "instantaneous," as applied to photography, he considers to be on the whole sufficiently well defined as "any photographic picture which, without blurring, clearly indicates objects in motion;" and assuming this as an intelligible definition, the author considers that the duration of an exposure must vary considerably, as the object photographed is in more or less rapid motion. In one case the duration of an exposure of one-fifth or one-tenth of a second may be permissible, whereas in another, one-hundredth part of a second will be scarcely sufficiently brief.

The essentials in an instantaneous shutter are grouped together under the following headings:—(1), It must be capable of giving a brief exposure. (2), It must be capable of giving a variable exposure. (3), Its construction must be such that, during exposure, it allows the lens to act with its full power and under its most favourable conditions. (4), Its construction and position must be such that the plate is as evenly illuminated as possible. (5), It must not shake the camera. (6), It must be as light and portable as is consistent with good work. (7), It must permit of the use of suitable diaphragms. (8), Its construction must be such that it cannot in any way derange the optical conditions of the combinations of the lens. (9), It should be simple to work, not liable to get out of order, and must of course be light-tight when closed. Each of these points is treated of with a reasonable degree of fulness, and a practical deduction is made therefrom. Certain manufactures come in for a

share of favourable comment, with which we have nothing to do. The little work is ably written.

HINTON'S BOOK OF PHOTOGRAPHIC LABELS.

As implied by the name, this book (issued by Hinton & Co., 38, Bedford-street, Strand, W.C.) is a collection of gummed and perforated labels of the most useful chemicals and "mixtures" used in the practice of photography. They have been compiled and arranged by the Rev. F. C. Lambert, and we can testify to their great utility. Many of the most useful are in duplicate; several contain numbers and others are left blank. They belong to that order of things of which we can truthfully say that no photographer should be without them.

THE A B C OF PHOTOGRAPHY.

London: The Stereoscopic Company, Limited.

SINCE the first edition of the *A B C of Photography* was issued, now many years since, photography has indeed undergone a well-marked process of evolution. The present edition (the twenty-second) is an entire reconstruction of its predecessors. Besides chapters on the development and general treatment of negatives and prints, it treats on portraiture, retouching, the arrangement of the dark room, lantern slides, enlarging, photo-micrography, instantaneous photography, and paper negatives. Issued primarily in the interests of the Stereoscopic Company, it is—necessarily, we suppose—not absolutely free from the taint of "shop," but it is a good, useful little volume for all that.

GRIMSTON'S INSTANTANEOUS SHUTTER.

This shutter fulfils the condition of having a reciprocating action without the slightest jar during its motion. It is constructed of such thin steel as (together with the sheath or frame in which it slides) to be capable of being inserted in the slit in a lens tube made for the usual Waterhouse diaphragms. The lens mount is thus left quite intact.

The exposure is effected by the rising up of the steel shutter, which raising is effected by the rotation of an arm connected with a spring, a revolution of the arm causing the shutter to rise and fall down with a smooth, gliding motion, and free from all jarring during the entire period of its motion, which may be either slow or imbued with extreme rapidity at the option of the user. The duration of exposure is regulated by very ingenious means; indeed, every part of this elegant little shutter has been carefully thought out and skilfully made. Its scope embraces everything, from the slow movement of an overloaded steamboat struggling against the tide to an express train dashing past.

Wratten & Wainwright, 38, Great Queen-street, London, W.C., are the manufacturers of this useful shutter, which can act either by a touch of the finger upon the trigger, or preferably by a pneumatic attachment. Several improvements have been effected in it since it was first introduced to the public, that now before us embodying all of them.

PATENTS COMPLETED.

IMPROVEMENTS IN PORTABLE PHOTOGRAPHIC CAMERAS AND APPARATUS RELATING THERE TO.

No. 2576. WYNDHAM HARRY PAYNE-GALLWEY, Cremona Works, Chelsea.—February 27, 1886.

My invention relates to portable photographic apparatus, known as "pocket cameras," and is designed to render the construction of the same sufficiently

compact to allow them to be carried in a portable case, and complete when in use, without loose detached parts; specific improvements being introduced into the chamber or drum containing the sensitive plates, and in its attachment to the camera, and also in the construction of "the shutter" and in other minor details.

My camera consists of the usual photographic camera lens and box, provided with a "shutter," by which instantaneous or any desired prolonged exposure of the sensitive plate may be readily effected, with which is combined a duplicate camera and field plate, adjacent to the photographic camera, by which a duplicate field may be rendered visible to the eye of the operator in use, similar to that which is thrown upon the sensitive plate of the photographic camera.

Both lenses are simultaneously focussed by means of an ordinary tangent pinion and rack. This arrangement serves the double purpose of easy adjustment to any required focus, which, upon being found, is fixed by means of a set screw, whilst at the same time, by the withdrawal of the lens-piece, the external dimensions of the camera are much reduced. A spring shutter is fitted to the mouth of the lenses, so that when withdrawn, the shutter closes over them, and protects them from dirt. The eye-piece of the field-finding camera is telescopic, and spring pressed, so that it may be pressed home, when not in use, to reduce the external dimensions, and which flies out to its proper position, when a detaining detent is released. Within the photographic camera box is placed the "shutter," which is in the form of two hinged doors supported on parallel axes on one of each of their respective edges, and placed at right angles to one another, conveniently vertically and horizontally, so that when one of the shutters—say that in a vertical plane—is rotated on its axis, and thus exposes the plate behind it, the other shutter—say that in the horizontal plane above the vertical shutter—is actuated by a spring, so as to fall rapidly, and immediately thereafter closes the aperture.

To the axis at the lowest edge of the vertical shutter is fitted a milled thumb nut, brought outside the box, and fitted around its axis with a spiral spring, which serves to bring the shutter always to its normal closed position in a vertical plane. The axis of the upper horizontal plate is also provided with a spiral spring, tending to make it close into a downward vertical position. A quadrant is affixed to this axis, bearing with its corner upon a grooved cam upon the axis of the other shutter. When the camera is set for operation, the lower shutter stands in a vertical plane, closing the aperture. The upper shutter is then set by hand against the reaction of the spiral spring, so that it stands horizontally with the quadrant on the axis of the upper shutter pressing against the cam on the lower axis. Upon rotation of the lower axis either by hand or automatically, as hereinafter stated, the sensitive plate is exposed until the cam allows the upper shutter to fall by the reaction of the spiral spring, when the aperture is at once closed. It may be noted that this combined shutter cannot be left open by accident and thus spoil a plate. The aforesaid axis of the lower shutter can be rotated by a rack and pinion, or any similar device which may be actuated more promptly by the mere pressure of a lever or button.

For the storage and supply of the sensitised plates, I attach to the side of the camera a cylindrical drum. The said drum is provided with a series of grooves vertical to the bottom of the drum, around the interior of the outer wall of the box, and around the interior boss, through which a stud fixed to the camera passes, by which the box is attached in place upon the camera. The grooves above described are so arranged relatively to one another that the sensitised plates are arranged partially tangentially to the inner boss, and thus accommodate a very considerable number of plates in the said box. The box is also provided with a series of indents in an external flange corresponding in number to that of the sheets of sensitised plates, with an additional serration corresponding to one blank space left solid between the boss and periphery in the body of the drum. The cover of the drum towards the camera is fixed relatively to the camera (the drum being free to revolve upon its central axis) and is provided with a slot corresponding in size to the edge and in angle to the position of the sensitised plates in the drum. This plate or cover is also provided with a spring catch engaging in the aforesaid serrated flange on the body of the drum, in order that the position of the said drum, when rotated, may always be exactly determined, so that the divisions in the drum are exactly opposite to the slot in the fixed plate. The slot in this slotted plate or cover is caused, when fitted to the camera, to correspond exactly to a slot in the side of the camera box, such slot being normally covered by a slotted sliding plate, which may be withdrawn or moved so as to cause all the slots to coincide, by means of a spring handle outside the camera box. When it is desired then to supply the sensitised plate to the camera, the sliding plate is withdrawn or moved, so that the slot in the sliding plate coincides with the slots in the drum and the camera, and a sensitised plate can then be delivered by gravity into the camera. When the photograph has been taken, the plate can be returned by tilting the negative plate into its own compartment in the drum. The drum is then rotated through an arc corresponding to a division, so that the next sensitised plate coincides with the position of the slots ready for the next photograph.

The serrations on the external flange of the drum, corresponding to the sensitised plates, are all numbered, and one serration bears the words "drum shut," indicating that position in which the slot of the rotating cover is opposite to the blank partition in the drum. A catch and pointer are provided, affixed to the camera, to indicate the successive numbers. This catch prevents the drum from being removed from the camera until the said pointer is engaged in that serration corresponding to the words "drum shut," in which position the drum cannot be turned any further (which avoids danger of double exposure of any plate), and may be removed, entire and closed, from the body of the camera, by the release of a nut. A duplicate drum may then be attached with a fresh supply, or the plates may be removed in a suitable manner, and a fresh supply of sensitised plates introduced.

It will thus be seen that as the drum can only be removed from the camera in the one position, namely, when the delivery slot is opposite and closed by the blank metallic partition in the box, absolute security is afforded against the admission of light to the sensitised plates before or after the photograph has been taken.

The whole form and external dimensions of my complete camera are, by the preceding construction, within the exterior dimensions of the aforesaid sensitised plate drum and without loose parts when in operation, so that the whole apparatus may be conveniently carried in a portable cylindrical case of the internal dimensions of the cylindrical sensitised plate drum.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at a meeting of the above Society, held at 5A, Pall Mall East, London, Mr. James Glaisher, F.R.S., President, occupied the chair.

The PRESIDENT said that before the minutes were read he wished the report of the Council, read at the previous meeting and since printed, to be adopted.

Mr. S. G. B. WOLLASTON moved that the report be adopted, with the exception of the clause about the satisfactory hanging of the pictures.

Mr. E. CLIFTON said that he would second this, for the sake of putting the matter to the vote.

Mr. T. SAMUELS did not think the report to be accurate; it said that there were 675 pictures at the exhibition and 198 exhibitors; according to the catalogue the number of exhibitors was 187 and there were 970 exhibits; the 115 exhibits excluded from the report were those on the table, and consisted of apparatus; much more skill was necessary in the designing of good apparatus than in taking pictures. He was against the adoption of the report in its present form.

The CHAIRMAN remarked that the report said that 675 frames were hung.

Mr. T. S. DAVIS moved an amendment that the report be adopted without alteration.

Mr. FRANCIS COBB seconded this, on the ground that no hanging committee ever did or ever could obtain universal approval for its work.

This amendment was put to the vote and carried; twenty-three voted for it and eight against.

The PRESIDENT wished the meeting would express opinions, as requested in the Treasurer's report, about printing the journal twice a year instead of monthly, to reduce expense. He (the President) thought that a monthly issue brought them into closer communication with their members.

Mr. F. INCE thought that the members had not much opportunity to discuss their own affairs; there was a tendency to snuff them out. Every one regretted that Captain Abney, who in the esteem of the Society stood second only to the President, had resigned the Vice-Presidency; he thought that some member of the Council should explain the matter to the meeting.

The PRESIDENT said that if they referred to the *Photographic News* they would see there a letter from Captain Abney giving his reasons for resigning. He resigned because the names of nominators of persons to fill vacancies on the Council were not to be published. A very full Council meeting decided that this should be the case. At the next meeting of the Council Captain Abney was present, and said nothing when the minutes of the previous meeting were read. He hoped he would withdraw his resignation.

Captain W. DE W. ABNEY said that he resigned because the names of the nominators were not added, and because his own nomination list of all the members of the Society was not printed. He had principles he would stick to, come what might, and he thought that the last Council was not constitutionally elected.

The PRESIDENT remarked that Captain Abney nominated all the members of the Society in a printed list to fill six vacancies. The custom had been that any one nominated should be able to fill the office; Captain Abney had nominated some who were dead, some who had failed to pay their subscriptions, and some who were no longer members of the Society. It was utterly impossible and impracticable to have done as he desired.

Mr. WOLLASTON moved that the election be set aside as irregular.

The PRESIDENT refused to receive the motion, because the election had been perfectly regular. New rules should be framed.

Mr. W. S. BIRD said that the rules under discussion had been framed in the most democratic manner possible some years ago, at a time when there was said to be too much power in the hands of the Council. He hoped that Captain Abney would reconsider his determination.

Mr. WOLLASTON said that a friend of his had been nominated to serve without his consent having been obtained.

The CHAIRMAN remarked that such should not have been the case.

Mr. R. M. LAWES stated that he had been so nominated, and he thought the last election to be illegal.

The PRESIDENT then pronounced the adjourned meeting to be closed.

Dr. W. F. DONKIN, M.A., Hon. Secretary, then read the minutes of the last meeting.

Mr. WOLLASTON moved, and Mr. W. H. HYSLOP seconded, that the minutes be not confirmed.

The PRESIDENT put the matter to the vote; twenty-two voted for and five against the confirmation; the minutes were accordingly confirmed.

The PRESIDENT then announced the discussion of Mr. J. B. Spurge's paper, read last month, to be the business before the meeting.

Mr. SPURGE said that he had a rotatory slide rule, connected with the problems in his paper, to bring before the meeting.

The PRESIDENT proposed a vote of thanks to Mr. Spurge, and called upon Mr. Bird to read Mr. Robinson's paper.

Mr. BIRD then read a paper by Mr. H. P. Robinson on *Exhibiting and Exhibitors*. The author said that the quality of the work on view at the annual exhibitions of the Society was improving. Sometimes the same man sent good and bad pictures to one exhibition, showing that the good ones were flukes; sometimes a picture would be hung above a door at one exhibition, and receive a medal at the next one; sometimes the reverse of this would take place. At the last Exhibition were five large frames to show what could be done with a particular maker's camera; as a juror he was not pleased at having to examine all the little pictures in those frames, all sent as an advertisement. Some of the foreign pictures were good but vulgarly mounted. An exhibition must first be made worth visiting by the public, and the pleasing of the exhibitors should be the second consideration. He thought that the names of the exhibitors should be known to the hangers, and that a few pictures should be hung depending for their interest upon the names of the producers: when a man constantly talks photography, writes photography, and tests everything to destruction, it would be interesting to see what kind of work he produces; an impartial hanger, not knowing his name, might reject his work. Persons not members of the Society should pay a little for the space their pictures occupy. When a veteran photographer sends in work, he thought they might in some instances hang his pictures, and be a little blind to their faults. Those who have not the best places on the walls should not attribute the fact to those much-abused persons, the hangers, who had their difficulties.

Mr. W. E. DEBENHAM supposed that the pictures taken with a particular camera were some rather remarkable instantaneous views; he did not see why they should be put away from the other instantaneous views, and he thought that the hangers had acted rightly. Some frames were said to be vulgar; in a matter of taste it was bad taste to call the selections of any one else "vulgar;" it was an unnecessary insult. Many persons liked black frames, and he did not see why they should be excluded. He protested against the suggestion that the hangers should show partiality.

Captain ABNEY said that various caps were flying about, and one of them fitted him, for he had once had a medal awarded for pictures which were subsequently not hung at all when sent to the Photographic Society of Great Britain. He sent in a protest to the Council about the bad work, of the hangers, and the Council civilly said that they were very sorry that such merit should have passed unnoticed; at the same time they made him a member of the hanging committee, of which appointment he was very proud. He appeared to perform his duties, and a gentleman said, "What do you want?" He replied, "I have come to hang pictures." The gentleman told him to go away, as he was not wanted, and added that the year before a fellow had sent some very good pictures, which were not hung. He (Captain Abney) explained that he was the man, and the other speaker stated that he was Mr. Robinson; that was their first introduction to each other.

Mr. T. S. DAVIS explained how the hangers would sometimes begin leisurely with their work, guided perhaps by a man of aesthetic proclivities, and afterwards, when time was running short and space more limited, would be guided in the rest of their work by a humble foot-rule.

Mr. WOLLASTON said that platinotype prints might be marred by being hung against a ghastly head upon pink paper; could not platinotype prints be hung by themselves? He was glad that the craze for bromide enlargements was dying out; he thought such enlargements not suitable for their walls.

Mr. BIRD remarked that Mr. Robinson had applied the word "vulgar" to one kind of mount alone. The hanging was difficult, and must be done rapidly; he thought that Mr. Wollaston would be an excellent hand upon the hanging committee.

Mrs. Mary Pritchard, Sir David L. Salomons, Bart., and Mr. Geoffrey W. Millais, were elected members of the Society.

The PRESIDENT announced that the ordinary meeting of the Society in April would be held on the 19th of that month; that is to say, upon the third instead of the second Tuesday.

The meeting then broke up.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At a meeting of the above Association, held on Thursday, March 3, at the Masons Hall Tavern, City, London, Mr. A. Mackie presided.

A question in the box asked: "As Boards of Arbitration have been formed to settle disputes in relation to various trades and professions, and are extensively used to escape the unexampled cost and delays of English law, should this Association inquire into the working and constitution of those boards and report thereon for the benefit of photographers?"

Mr. A. COWAN thought that inquiry should be made.

Mr. W. H. HARRISON believed that the appointment of such a board would save photographers the expenditure of much money; in the *Times* law reports of that day was much about such boards, which now had an average of four cases to settle daily; in business agreements a clause was now often inserted agreeing to refer disputes to one of the boards; the board pledged the contending parties not to go to law without its consent.

Mr. W. M. ASHMAN said that the question before the Association at the previous meeting about enlargements might well be referred to such a board. The photographic societies of Great Britain should be consulted about appointing official arbitrators.

The CHAIRMAN remarked that photographers, as a body, had no cohesion whatever, and the society supposed to chiefly represent them, perhaps represented them least.

Mr. A. L. HENDERSON would like to hear opinions from photographers about the appointment of such a board; it was a very important subject.

The HON. SECRETARY thought the subject deserved to be brought up at the next Convention at Glasgow, when a representative of every photographic society in the kingdom would be present.

Mr. HARRISON said that the way to get such a proposition carried through would be for one photographer to take the subject up and make the question his own, doing all the work and correspondence until he had the honour of getting a Board of Arbitration established. As an amateur he had no personal commercial interest in the matter.

Another question was: "Do prints mounted on waterproof mounts cockle? Why not mount proofs with waterproof composition?"

The CHAIRMAN said that undoubtedly they cockled.

Mr. J. HUBERT had had a bad experience with waterproof mounts; prints could only be fixed upon them with gelatine.

Mr. HENDERSON had soaked ordinary mounts in from two to five per cent. of paraffine wax dissolved in benzine. Sometimes he applied this solution after the mounting; it soaked right through the print.

Mr. HUBERT sometimes mounted and dried prints upon boards curved in the opposite direction to that which they would have a tendency to assume after drying.

Mr. COWAN said that good glue was better than inferior samples of gelatine for mounting. All the best professional mounters, including Fox, used glue.

Another question was: "Can wood-spirit be used to precipitate gelatine?"

Mr. HARRISON remarked that pure wood-spirit or methylic alcohol, free from acetone, was rarely seen and very expensive. Ordinary samples were frequently far from pure. It boiled at a lower temperature than ethylic alcohol, and had some useful peculiarities.

Mr. HENDERSON remarked that a commercial specimen before them would give spots if used for precipitation; he, however, knew a New York photographer who invariably used wood-spirit for precipitating emulsion.

Mr. ASHMAN called attention to Mr. T. S. Norris's method of preserving strong solutions of pyrogallol by keeping the upper part of the stock bottle filled with common gas; he had seen a solution which had been kept quite colourless by that method for two years at the City and Guilds Technical College.

Mr. COWAN said that a weak solution could not be kept in good condition by the method stated.

The meeting then broke up.

CAMERA CLUB.

THE subject arranged for the Thursday evening meeting of members on March 3 was a demonstration of their carbon process by the Autotype Company. Mr. F. Machell Smith occupied the chair. The attendance was excellent. Both Mr. Sawyer and Mr. Bird were present and spared no pains to make the demonstration thorough and interesting. Every necessary appliance had been brought to the Club, and, in addition, a fine selection of autotype pictures was on view.

Mr. SAWYER introduced the subject by a lecture giving the history of autotype, and then proceeded, with the assistance of Mr. H. J. Burton, to the development of the exposed tissue on single transfer, temporary support, and on collodionised glass. Some very successful results were turned out, the rich colour and fine quality of the pictures obtained by the process proving very attractive.

After the demonstration Mr. J. E. AUSTIN suggested that calcium-chloride tubes might be used with advantage to preserve sensitised carbon tissue. He did not quite understand how Mr. Sawyer proposed in some cases to obtain superior results by taking pictures through the glass side of the plate. He thought the frequent air bubbles in the glass would spoil the negatives. He would like to know whether it were possible to get rid of the glazed surface from the carbon print after stripping.

Mr. W. H. HYSLOP asked what effect gas fumes had upon the tissue.

Mr. V. C. DOUBLEDAY had attempted to make lantern slides in carbon, but had met with great difficulties, and had not been successful. He would like to know the simplest way of going to work.

Mr. G. DAVISON suggested pressing in contact with ground-glass to give a matt surface to the stripped carbon print.

Mr. MACHELL SMITH thought grained zinc would be preferable.

Mr. SAWYER said they had been experimenting in regard to gaining a matt surface. The processes named would no doubt secure the end in view. In regard to Mr. Austin's inquiries, he thought that the tissue did not require the calcium-chloride tube. It might possibly crack if kept in that way. In referring to the superior results obtainable in securing reversed negatives, he meant to convey that improved gradations were to be got by attention in the intermediate process of taking a transparency. The quality of the negative in regard to density could be improved. In reply to Mr. Hyslop, it was necessary to dry the tissue free from gas fumes or it was rendered insoluble. Lantern slides were a weak point. If a negative were the least thin no result bright enough was obtainable.

The proceedings terminated with a hearty vote of thanks to Messrs. Sawyer and Bird and their assistants.

On Thursday, March 17, the subject is *Collodio-Bromide Emulsion*, with demonstration by Mr. H. J. Gifford.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

THE ordinary monthly meeting of the above Society was held on Tuesday last, in the Masonic Hall, Cooper-street, Manchester, Mr. S. F. Flower in the chair.

The following were elected as members:—Messrs. Thomas Carter, Leslie E. Clift, Geo. Wm. Cook, J. Guilford, Bernard S. Harlow, Arthur Holt, John Irvine, George Moseley, J. Partington, A. Piekston, and John Weir.

Mr. W. RUSSELL exhibited an improved changing bag, the novelty of which consisted of a window of stained parchment. This want, he said, was much felt, and could not be had from the makers.

Mr. T. STEVENTON gave a *Demonstration of Carbon Pigment Development*, but previous to doing so he gave a slight outline of the early history of this process. He then proceeded to develop the prints.

CARDIFF AMATEUR PHOTOGRAPHIC SOCIETY.

AT the recent monthly meeting of this Society, the President in the chair, Messrs. Frederick Heitzman and C. J. Emery were elected ordinary members.

Mr. JESSE WILLIAMS gave an interesting lecture on the *Theory of Development* [this will appear in a future number].

The PRESIDENT, in proposing a vote of thanks to Mr. Williams for his interesting lecture, alluded to the importance of becoming *an fait* as to the action of photographic chemicals. He was afraid many of their members worked by mere matter of rote, and did not take the trouble to ascertain for themselves "the why and the wherefore." He urged them to give more attention to minor details; it was of great importance if they wished to become successful photographers.

Mr. C. F. GOOCH seconded the vote of thanks.

The members were interested in the President's account of his recent visit to London and the welcome afforded him by the Camera Club. Arrangements are pending for a visit from Mr. T. C. Hepworth. The President also promised a lecture for next month, illustrated by limelight.

The HON. SECRETARY read a communication from Mr. John Storrie, the Curator of the Cardiff Museum, granting permission to the members to photograph anything of interest, and proffering his kind assistance.

Acting upon a suggestion made by the Hon. Secretary, the Committee of the Cardiff Free Library have courteously added to their lending department a valuable collection of photographic works.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of the Association was held at the Queen's Hotel on Wednesday, February 16,—Colonel Playfair, Vice-President, in the chair, and there was a large attendance, a paper on *Film Photography*, by Mr. Manfield, having been previously announced.

The HON. SECRETARY (Mr. H. A. Hood Daniel) intimated that it would be desirable to pass the printed minutes of January and February at the next meeting, as the issue of the former had been much delayed by the yearly rearrangement of the advertisements.

Mr. E. BRIGHTMAN was called on by the CHAIRMAN to read Mr. Manfield's paper, that gentleman being absent [see page 152].

Mr. J. PHILLIPS inquired as to time required for final washing of the negatives.

Mr. BRIGHTMAN stated that the time required was much less, as the water got at the film from both sides at once.

Mr. BOORNE remarked that the Eastman people stated fifteen minutes as being sufficient for that operation.

Rev. H. B. HARE inquired why the ammonia should attack the film.

Mr. BRIGHTMAN replied that it was the combined action of the ammonia and pyro which was referred to as *toughening* the film of gelatine too much.

Rev. H. B. HARE considered that if a film was likely to frill at all such was less likely with ammonia than with soda.

Mr. BRIGHTMAN said it was very noticeable how many were now writing and complaining of the frilling of plates, but doubtless they were in most cases using Beach's developer, a very potent producer of that trouble.

Rev. H. B. HARE had experimented with the Beach developer, but had not succeeded so well as with ammonia.

The CHAIRMAN had not succeeded with the Beach developer anything like so well as with ammonia, his chief complaint being that it stained the film so much.

Rev. H. B. HARE considered that the chief objection to ammonia was its considerable and rapid reduction in strength.

Mr. STEVENS advocated keeping it in a ten-per-cent. solution, a very convenient mode for obviating the defect Mr. Hare mentioned.

Mr. DANIEL said that he considered a ten-per-cent. solution somewhat awkward, say, in the case of a solution desired to be made of seven to one. He much preferred the mode of diluting ammonia immediately on its receipt with equal bulk of water and so labelling it. Any strength solution desired could then be made.

Rev. H. B. HARE saw a good mode recommended for keeping the stoppers of bottles tight, namely, to place them upside down in a pan of water.

The CHAIRMAN proposed a vote of thanks to Mr. Manfield for his very interesting and instructive paper, and could not help feeling that after seeing the very beautiful specimens exhibited the days of glass were numbered.

The vote of thanks was passed unanimously and cordially to Mr. Manfield for his instructive paper, which was listened to with much attention.

The CHAIRMAN proposed that, as the Association Room was open to members at any time during the day, the following papers should be regularly taken and kept on the table:—*THE BRITISH JOURNAL OF PHOTOGRAPHY*, *Photographic News*, *Amateur Photographer*, and *The Camera*, which, having been duly seconded, was carried, after which the meeting was adjourned to March 16.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

AT the meeting held at Myddleton Hall, Islington, N., on Tuesday, March 1, Mr. J. Traill Taylor, President, in the chair, Messrs. W. Ackland, W. Bedford, E. Dunmore, E. W. Foxlee, D. W. Hill, J. Martin, and G. W. Shadbolt, members of the former North London Society, were elected honorary members, and Messrs. Harold Inray and H. H. Dimmock were elected as ordinary members.

A letter was read from Mr. Eric H. Johnson, of Putnam, Conn., U.S.A., offering to exchange prints with members of the Society.

A question from the box was read, asking the best method of making oxygen.

The PRESIDENT described the ordinary method of making oxygen from chlorate of potash and manganese.

Mr. E. CONRAD said that the addition of chloride of sodium had been recommended.

Mr. E. CLIFTON drew attention to the fact that oxygen was now being commercially produced by the Brins Oxygen Company, by the barium-oxide process, at a very cheap rate; oxygen so prepared did not contain chlorine, and therefore did not destroy the gas bags.

A question was then read, inquiring the cause of and remedy for collodion emulsion which gives crapy lines on coating the plate.

Mr. A. MACKIE suggested that either the solvents used were not of sufficiently high specific gravity or that the pellicle had not been sufficiently dried before redissolving. He added, that with some samples of pyroxyline this fault was more likely to occur than with others.

Mr. L. MEDLAND showed a new lens mount he had had constructed for converting his rapid symmetrical into a wide-angle lens. He also showed an auxiliary focuser for use in instantaneous work.

In the adjourned discussion on Mr. Taylor's lecture, Mr. F. W. COX asked whether the composition of the glass used in the manufacture of lenses influenced their rapidity, focal length and aperture being the same.

The PRESIDENT replied that, provided the glass was colourless, there would be no difference.

A MEMBER said that he had a portrait lens which gave a flare spot under any circumstances, and wished the President to give the reason.

The PRESIDENT thought this hardly possible, and suggested that the lens be brought to the next meeting for examination.

Mr. MACKIE said that, considering the importance of the lens, it was astonishing how ignorant photographers were of the simplest facts concerning its properties and use, and suggested that a few axioms applicable to lenses in general, whatever their construction might be, should be published in one of the photographic journals.

A large number of interesting slides was then shown by means of the optical lantern.

The next meeting will be held on Tuesday, March 15, when Mr. Edgar Clifton will deliver a lecture on *Cameras, Ancient and Modern*. Visitors are invited.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting of this Society was held at the Greyhound Hotel, Dulwich, on Wednesday evening, March 2.—Mr. Wolff in the chair.

After the usual business had been transacted, Mr. WALKER gave a description of the Eastman stripping films and their manipulation. The whole of the processes were shown practically by Mr. Jackson, the Company's demonstrator, and were entirely successful. Mr. Walker showed a series of reproduced negatives on the films made by Mr. A. Pringle, which were quite equal to any on glass.

The next meeting will be on Wednesday evening, March 16, when a communication on bromide-paper will be made by Mr. A. Ryder.

Correspondence.

227 Correspondents should never write on both sides of the paper.

FEBRUARY MEETING OF THE PHOTOGRAPHIC SOCIETY OF FRANCE.—GELATINO-CHLORIDE PROOFS AND EMULSIONS.—A NEW STRETCHER.—A TRIPOD WITH ARTICULATE CENTRE.—ANOTHER MANUFACTURER OF DRY PLATES.—BUSINESS DEPRESSION.—EASTMAN'S PAPER AND TONING OF PRINTS BY PLATINUM.—A NEW SHUTTER.—A SMALL CAMERA.—PORTRAITURE BY ELECTRIC LIGHT.—REVERSIBLE FILMS.—SILVERING GLASS PLATES.

The Photographic Society of France held their February meeting on Friday evening last, the 4th instant, M. Davanne in the chair.

M. Tondeur presented a collection of positives on glass, made by his new gelatino-chloride emulsion. He said he was very happy to be able to add that it was a Frenchman who was the first to present gelatino-chloride emulsions to the French Society of Photography. Here a storm of interpellations fell upon the unhappy author. MM. Franck, Guilleminot, and Stebbing said that they had manufactured gelatino-chloride plates, and that proofs had been presented to the Society. M. Tondeur took to the safe side by saying that if the results from gelatino-chloride emulsions had been exhibited, no emulsions ready to be used had been shown. M. Tondeur states that he has discovered a new and novel method of making emulsions in full light, and that upon going into his dark room rapidity is acquired instantaneously. These emulsions can be kept for a length of time without decomposition. M. Tondeur had promised to endow the public with his secret, by divulging it to the French Society of Photography, and it was even published upon their programme; but at the last moment this gentleman preferred to keep his secret to himself, and disappoint the members who went to the *séance* on purpose to learn another method.

M. David presented a stretcher for films composed of a brass frame, as in those already known, such as Londe, Eastman Company, &c. The only thing new is that no flaps are required to turn down upon the film. The film need not be larger than the size required, and is held by the following expedient:—Round the edge of the brasswork frames M. David had the idea to punch a line of holes; the rough surface of these holes act like pins, prick into the film, and hold it firm. When the stretcher is put into the dark frame, the door being closed pushes upon the stretcher and flattens it down; this flattening makes it become larger, and causes the

film or paper to become stretched like a drum-head. For myself, I cannot recommend stretchers which make holes in the sensitive surface. The only inconvenience I see in the folding-down ones is that the films must be purchased of a larger size than required, thus making them a little more expensive.

M. Horn presented a camera tripod with an articulated contrivance in the centre, such as was presented to the Society in the month of December by M. Lebreton, and of which I gave a full account in one of my letters to THE BRITISH JOURNAL OF PHOTOGRAPHY. Since the value of that addition by M. Lebreton has been established, other inventors claim the honour of having invented it; one among the rest claims the honour for his old master, one of the first manufacturers of photographic cameras, long ago dead and reposing from his labours. As it is, the dodge is a good one; and if it has been forgotten and in disuse, it must be brought before the photographic community again as a very useful addition to the well-known tripod.

M. Offert, a new manufacturer of gelatino-bromide of silver plates, presented specimen packets to the members in order to be experimented upon.

Plates are at such a low price on the Continent, and makers so numerous, and business so bad, that plates of any brand and at whatever price are equally disdained. The proprietor of one of the best houses in Paris, on being asked to give work to an operator, replied that he had been obliged to discharge hands, and that he could not find work for the operator remaining. On being asked the cause of this dearth of customers, he replied that although photography had made such rapid strides in beauty and artistic taste during the last two years, it appears that the public has become indifferent altogether to photography. Formerly, said he, albums could be seen upon every parlour table; now coloured illustrated journals take their place. Amateurs torment their friends to sit as models, photographers bother actresses and artists, as well as prominent personages, to honour them with a sitting; so at last, if things go on in the same way, we shall be obliged to fee our customers instead of their paying us. A little exaggeration can be accounted for, but this is not the only instance.

M. Chenevière presented a collection of positives on Eastman's paper, as well as some enlargements having a very agreeable tone, having been passed through a bath of platinum. To M. Vidal is due the popularisation of this method of toning, which he described as follows:—In order to make positives printed upon Eastman's paper more durable, they can be toned with platinum, the same as those printed upon albumenised paper are toned with gold. After having developed the image in the ferrous-oxalate bath, it is thoroughly washed in water acidulated by acetic acid, and it is then immersed in the following solution:—

Water	2000 parts.
Bichloride of platinum	1 part.
Hydrochloric acid	25 parts.

The proof can be left in this bath from twenty minutes to half an hour. It is well to print the proofs a little deeper in shade, as they lose a little of this vigour in the toning bath. If the operator is not sure of the action of the platinum salt upon the proof, let him cut off a small piece of the proof, and immerse it in the following solution:—

Water	1000 parts.
Bichloride of copper	120 "

If the image is covered with platinum, it will resist the action of this bath, but if it has not been properly toned it will fade away completely. The paper need not be thrown away, as the image can be redeveloped by plunging it into the ferrous-oxalate bath. Not only will it redevelop in all beauty, but it will give a brighter and a better image than it did after its first development. The action of the platinum toning solution ameliorates and modifies the tone or colour of the prints, which take a fine bluish-black colour. After having fixed and well washed the proofs, they must be allowed to remain at least ten minutes in the following solution:—

Water	1000 parts.
Alum	50 "

M. Mareo-Mendoza presented a new shutter of his invention, with which he declared he was able to make different exposures, from instantaneous to minutes. This instrument is made after the principle of Watson's rapid shutter; when one flap rises up another falls down, and thus the obturation is obtained. M. Londe objected to this system, as being faulty in the extreme. He said that it was practically impossible to avoid a shaking of the camera with a shutter which opens, and at the moment when the image is half exposed lifts a catch, which liberates a second flange to close the lens. The inventor, with great tact and dexterity, turned the laugh on his side, by wisely saying that he did not pretend to say that his shutter was superior to that of M. Londe, which was a commercial article.

M. François presented a small camera for instantaneous work, 2 × 2. The camera is intended to be held in the hand during the operation. The lens is of a fixed focus, therefore automatic; an instantaneous shutter is adapted. Above the working lens is another small lens, which acts as a camera obscura. The image is reflected upon a ground-glass inserted in the top of the camera, so that the position of the object can be ascertained, and its movements seen all the time. This ground-glass is protected by a kind of covering lying flat when closed, but when opened

forms a sort of tent or shade. M. Français has given it the name of kinégraph.

Professor Stebbing presented some magnificent proofs obtained by a new combination of the electric light in the studio of M. Chary (late Walery), of Paris. The proofs were so to the taste of some of the members, that notwithstanding the expressed wishes of the President to return them several were missing. The French Society would do well to copy the English societies, in having a book in which to write the names of members and visitors, and by whom introduced; these petty larcenies would not occur so frequently; strangers being admitted up to the present without any control. Readers of THE BRITISH JOURNAL OF PHOTOGRAPHY interested in electric lighting can read a short description of M. Chary's method in one of my former communications.

M. Balagny presented some very fine specimens of his reversible films. M. Bory sent in a communication on the silvering of plate glass. It being very late it was ordered to be published in the *Bulletin*.

25, Rue des Apennins, Paris.

PROF. E. STEBBING.

RETOUCHING.

To the Editors.

GENTLEMEN,—With the sentiments expressed in last week's JOURNAL by "Over-weary" I can heartily sympathise, having often felt that way myself.

Of course, employers naturally expect a maximum of work with a minimum of pay, and that is responsible for a good deal of the wretched retouching produced. When a man is expected to finish so many heads a day, be they rough or smooth, he cannot have any time to *think* what is best to be done, but must simply put the polish on as rapidly as possible. To stick at that polishing process day after day, and week after week, is almost maddening in its monotony. Such work (though often regarded as the easiest) is dreadfully wearing, not only to the eyes but to the nerves and body generally, and should certainly be better paid for than it frequently is.

I should like to ask Mr. Barrett what he considers a fair day's work? Doing the negatives well, and working, say, from nine a.m. to six p.m., with an hour off—I am well aware that some negatives take twice as long as others, but taking the rough with the smooth—how many *carte-de-visite* vignette heads ought to be done in the time?

On applying for a situation I have been told that unless I could do a certain number of heads per diem I would not suit. Is that sort of thing quite fair? Then, after literally slaving all the summer, as the winter comes on you may be informed that the small amount of business doing does not justify the retention of an expensive assistant, and, with many regrets, out you go. That sort of thing is hardly an encouragement for men to persevere in the profession.—I am, yours, &c.,

HYDRA.

To the Editors.

GENTLEMEN,—In last week's issue of THE BRITISH JOURNAL OF PHOTOGRAPHY there are two of your correspondents who have very kindly mentioned my name, and to whom, with your indulgence, I wish to reply. One, "Over-weary," has only added his testimony to the justice of some of my remarks in a former issue of your JOURNAL, and for which I beg to thank him; but the second, Mr. H. J. Gorfin, "calls me over the coals" because I said "that Mr. Williams," of Regent-street, "retouched his negatives." Whenever I am wrong I am only too happy if any one will kindly correct me. Personally, I have always regarded Mr. Williams as a photographer second to none, and I cannot find anything in my article to the contrary, but I hope Mr. Gorfin will forgive me if I stick to my opinion regarding Mr. Williams retouching his negatives. As I said, I *may* be wrong, and if Mr. G. Croughton (an artist of the time in question, and also one whom I regard as an authority on retouching) will condescend to tell me that I *am*, I will be very happy to acknowledge my error and make the *amende honorable*.—I am, yours, &c.,

REDMOND BARRETT.

SULPHURATION OF PLATINOTYPE PRINTS.

To the Editors.

GENTLEMEN,—I do not wish to trouble you further in reference to this controversy; it is evident to me that, as of old, the people will be deceived, and that they "love to have it so." Very well, let them. But I wish you to place on record that in compliance to a request by me to Mr. Pringle that he would state publicly the grounds for his public statement (absolute) in your pages (December 3, 1886), he has sent me a private letter, in which he says: "You appear (*sic*) to find fault with my statement that the 'metal platinum forms but a small proportion of platinotype print.' Will you kindly weigh it, and then say what proportion of the total weight is due to the paper and what to metallic platinum?" Now, gentlemen and readers—those who *do read*—I want you to turn to Mr. A. Pringle's letter, published December 3, and then to form your opinions upon the justice and honesty of the combating parties. If I were to write a "trilogy of letters," I could not come up to—or go down to—the level of this remarkable interpretation so long forthcoming. Again I say, *read the letter from Mr. Pringle, published December 3*.—I am, yours, &c.,

HERBERT B. BERKELEY.

P.S.—I should add that Mr. Pringle further states that he doubts the composition of the image—especially *since* writing the "absolute statement," but he does not give any reasons. There is an error in eighth line, second paragraph, of my letter, February 19—for any read *no*.

LIMELIGHT MATTERS.

To the Editors.

GENTLEMEN,—I shall be glad if you will allow me to say, in answer to Mr. Lewis Wright's letter of last week, that the automatic valves in question do fulfil their title by acting perfectly when attached to the *ordinary* pressure gas cylinders, even when all the taps of jets, &c., are turned off and the regular valve is unscrewed and open. This I tried to express in my remarks when I said "that a gas cylinder with an automatic valve attached is practically the same as an average weighted gas bag." I shall have much pleasure in showing those interested the automatic valves in operation if they will call at 406, Strand, London, and, providing a few hours notice is given, will have a triple or biunial lantern set up in the dark room with *identical* optical systems and jets, so that the light from the gas cylinders and gas bags could be compared. When using *mixed* jets with the extra high-pressure gas cylinders recently introduced, it is somewhat more difficult to control the flow of gas and prevent it accumulating when a tap is turned off as it would be in dissolving; but when it is considered that the pressure in the steel bottles is 1500 pounds to the square inch this is not to be wondered at, and notwithstanding the difficulties to encounter there is every chance that the inventor (Mr. R. Beard) will succeed in overcoming this. As, however, an iron bottle or gas cylinder twenty-eight inches long and five and a half inches diameter can be filled with twenty cubic feet of gas at a pressure of about six hundred pounds to the square inch, and as the valves act perfectly in checking the flow at this pressure, there seems no necessity when required for dissolving to have the extra quantity of gas pumped in the cylinders.—I am, yours, &c.,

March 7, 1887.

G. R. BAKER.

EOSINE IN ISOCROMATIC PHOTOGRAPHY.

To the Editors.

GENTLEMEN,—We need trouble you with no reply to Mr. Hyslop's letter in your number of February 25. His "statement" is, this time, quite correct; there has been no transfer of the patent, therefore he would be hardly likely to find a record of the transaction. Nevertheless, it is a fact that we are the sole licencees for the use of eosine in the gelatino-bromide process for Great Britain and the Colonies.

With regard to Dr. Vogel's specification which has just been published, we have to inform your readers that the application has been opposed and all proper steps taken to prevent an English patent being granted, on the ground that it is a direct copy and infringement of Tailfer & Clayton's patent, dated January 8, 1883, under which we hold our licence.

In reply to the suggestion of a correspondent, Mr. H. A. Lewis, that we should supply the eosine preparation for the purpose of rendering ordinary plates isochromatic by the bath process, we beg to explain that we do not use or recommend this method, which is troublesome and complicated, for the simple reason that plates so prepared will not keep, whereas, by our method of making the emulsion itself isochromatic in the first instance, the plates are not only of superior quality, but they also have all the good keeping qualities of the best gelatino-bromide plates of the ordinary kind.—We are, yours, &c.,

B. J. EDWARDS & CO.

The Grove, Hackney, London, March 8, 1887.

A DISCLAIMER.

To the Editors.

GENTLEMEN,—I was as much surprised and puzzled as your correspondent Mr. England, at seeing the curious remarks said to have been made by me at a recent meeting of the Leeds Photographic Society. I certainly did not say amateurs had a monopoly of artistic treatment of their subjects, or any advantage whatever over the professional, except in so far as they may have a greater freedom of choice of subjects; that is, they can refrain from trying to make pictures of what is unpicturesque.

With regard to the second statement fathered on me, what I *did* say was, that, having had to pass some time in a certain not very high-class establishment at one time, and noticing the general absence of beauty (to use a mild term) in the class of persons who frequented it, I thought the professional photographer was to be pitied who was expected to invest such rooms with artistic appearance. On this point I may mention that yesterday I met a professional friend, who, after telling me he had had a hearty laugh over my (supposed) observations, added, "But what you say is quite true, and had I been present I should have spoken even more strongly on the subject."—I am, yours, &c.,

12, Park-street, Leeds, March 8, 1887.

A SUGGESTION.

To the Editors.

GENTLEMEN,—The system of piracy, as carried on now and for years past, demands a remedy. Of course, the remedy is to have any portrait registered, but in daily practice the time taken up in sending to the office in London is an objection. The plan I offer is, that it should be possible to register a photograph in any town at the stamp office. It would bring in a considerable revenue, as, doubtless, it would be taken advantage of by all respectable photographers. If you think it worth attention, please put it in your valuable JOURNAL.—I am, yours, &c.,

Cheltenham.

AN ARTIST.

Exchange Column.

* * No charge is made for inserting *Exchanges of Apparatus in this column*; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange half-plate Lerebour portrait lens, with Waterhouse diaphragms, for half-plate wide-angle rapid rectilinear lens.—Address, J. GOODMAN, New-street, Farsley, near Leeds.

Will exchange quarter-plate mahogany camera, one single dark slide and double combination portrait lens, for strong tripod stand suitable for 12×10 camera.—Address, TRIO, 123, Southgate, Gloucester.

Will exchange a Lawley's portrait lens, with sliding-body camera and one single slide, for Lancaster's quarter-plate instantograph.—Address, W., 8, Westfield-terrace, Sheffield.

Will exchange a dark photographic carriage on wheels, completely fitted up (cost £10). Wanted, half-plate long-focus folding camera, with three or more double backs.—Address, J. W. SMITH, 71, Seatgate, Stamford, Lincolnshire.

Vogel's carte and group lens, two and a quarter inches diameter. Wanted, offers in ferrotype stock.—Address, Mr. ASHLEY, 29, East-street, Stonehouse, Devon.

Wanted to exchange, phantom shutter (hardly used), suitable for Ross' 5×4 rapid rectilinear lens, for Watson's cyclist's tripped and stand.—Address, E. MARKS, Royal Aquarium, Westminster, S.W.

Wanted to exchange, gem camera, nine lenses, to take thirty-six pictures on 7×5 plate (cost eight guineas), for a good whole-plate rectilinear lens.—Address, A. GATES, Photographer, Market-street, Aberdeen.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although no necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

PHOTOGRAPHS REGISTERED:—

W. D. Valentine, Dundee.—Two group photographic views.

G. & H. Hall, 26, Westgate, Wakefield.—Photograph of testimonial to W. Aden Cars.

PAINTER.—Unless we knew the focus of the front lens we could not answer. But it will cover a whole plate at any rate.

AMOURLETTE.—Try another sample of paper having a less highly glazed surface, or dry the prints between blotting-paper, so that they do not curl up in drying.

A. WILSON.—With that dusting-on formula you ought to succeed. Probably you do not allow the plate, after being exposed, to remain sufficiently long in a damp place.

HYPO.—1. Any strong tricycle will answer, but we cannot indicate a special make.—2. Brown holland will answer.—3. Advertise for an artist. There are many who would willingly undertake the work.

RAPID PARAGON.—1. Yes, there is a difference in the construction.—2 and 3. The components of either of "Rapids" used as a single lens will be all that you require.—4. The bayonet joint is the more convenient.

HYPO.—The spots are evidently due to sulphur. Probably air-bells have become imprisoned between the prints while in the fixing bath, or perhaps in the first washing water. The injury is quite as liable to occur in the latter as the former.

S. S. S.—1. To remove the stains try sulphuric acid (diluted) and alum.—2. Have the background repainted. We are preparing an article on the subject.—3. Either of the lenses will answer, but we would give preference to the one having the shortest focus.

C. J. S. B.—Write to Messrs. England Brothers, Charles-street, Royal-crescent, Notting Hill; they are the printers. Husnik's work on the collotype process (in German) may also be of service to you. It may be procured through Messrs. Triibner & Co., Ludgate-hill.

F. JOHNSON asks: "Can you please to inform me, through the 'Answers to Correspondents,' if there is any method of securing rich purple tones with Cowan's chloride plates for transparencies? and if so, kindly give formula, and oblige."—Perhaps Mr. Cowan will kindly supply the desired information.

LUX.—Probably pure hydrogen, obtained by dissolving zinc in diluted sulphuric or hydrochloric acid, would serve the purpose. The special virtue in employing dry pyrogallic acid in the way described lies in its being always fresh. It is usually measured in a small scoop when lifted out, instead of being weighed. The strength can always be nearly estimated.

J. HARRIS inquires: "Will you kindly give an arithmetical example to show how to divide the diameter of stop into the focal length of lens?"—We reply: Having ascertained the focus of the lens—which is, say, ten inches—and the diameter of the aperture in diaphragm—which we shall assume to be half an inch—you have next to compute how many half inches there are in ten, and then mark that particular stop as $\frac{1}{2}f$.

H. H. NEWMAN asks: "Would you kindly let me know, through the JOURNAL, where I can get a good pyrotechnic lamp for artificial lighting, also a magnesium lamp for the same purpose?"—Those who employ pyrotechnic compounds usually have a lamp constructed according to their special requirements. Mr. F. W. Hart, of Kingsland, and Messrs. Solomon, of Red Lion-square, both supply magnesium lamps.

W. S. writes: "Will you kindly inform me, through the JOURNAL, the cause of the film of the enclosed negative going as it has? I developed with the developer given by Mr. Pringle on page 90 of the JOURNAL, with the exception that instead of using bisulphite of potash I used sulphurous acid and carbonate of potash. The exposure was eight seconds with a wide-angle lens."—The appearance of the film is due to incipient frilling, brought about, no doubt, by the employment of an excess of potash. This our correspondent can prove for himself by trying some of the same plates with a developer made up according to the formula given by Mr. Pringle.

J. H. T. ELLERBECK writes: "In the report of the Liverpool Amateur Photographic Association, just issued, my name appears as an honorary member. As this is open to misconception, I ask you to allow me to state that, although repeatedly offered this, I have most emphatically refused the honour (?), the acceptance of which, had it been of any use to me, would have been an acknowledgment of the legality and justice of their late decision."

J. H. J. says: "I wish to enlarge from quarter and half-plate negatives to about 12×10 on bromide paper by daylight. Would you kindly tell me what kind of lens would be the best? I have a Ross' half-plate rapid symmetrical, and my camera racks out to sixteen inches. I have never done any enlarging."—The lens named will do quite well, but in enlarging from the half-plate negatives a stop will no doubt be required.

A MEMBER of the Bolton Photographic Society informs us that, *apropos* of the report given in our JOURNAL last week, the awards at the annual *soirée* were as follows:—No. 1, Photographs taken during the season: 1st, Mr. E. N. Ashworth; 2nd, Mr. C. K. Dalton. No. 2, Photographs taken at outdoor meetings this season: 1st, Mr. C. K. Dalton; 2nd, Mr. W. Laithwaite. As regards No. 3, that for Lantern Transparencies, there was practically no competition.

KU KLUX.—It will quite well suffice if the small camera be placed on a strip of wood of twelve to eighteen inches long, with pieces at either end against which the camera may be placed in succession to ensure parallelism. It is only when a very near object is to be photographed that the bars are required to converge towards it. Eye-pieces of the kind spoken of cost seven shillings and sixpence the pair, unmounted. If you fail to obtain them, write again.

W. D. asks: "Will you kindly inform me if good methylated spirit will answer in the place of the large quantity of alcohol mentioned in Henderson's cold precipitation process for making gelatine emulsion? I mean the eight ounces of alcohol with which the gelatine and silver are mixed, and which is nearly all recovered."—Methylated spirit will answer the purpose quite well. Of course what is known as "methylated finish" will not do at all. This latter is often sold for the former by some oilmen.

A CONSTANT READER (Hammersmith) writes thus: "Will you kindly inform me, through your valuable JOURNAL, whether a plate exposed, say, fifteen seconds on a day like last Saturday out of doors would take a long time to develop and only produce a picture without contrast?"—As we do not happen to know the quality of the light in our correspondent's neighbourhood on the day named, or the lens employed, or any other particulars, we are unable to give an opinion. We surmise, however, that the plate was under exposed.

SPECTRUM puts the following query: "How are the glasses in a lens fastened together?"—In reply: Lenses are usually cemented together with Canada balsam; occasionally castor oil has been used. The lenses may be cemented as follows:—Make the glasses thoroughly warm, then place a drop of the balsam in the centre of one, by preference the concave—supposing one to be concave; next press the other upon it so as to force out all the balsam possible. After this the lens must be placed in a warm situation till the balsam becomes hard.

WASHING MACHINE writes: "Would you enlighten me, through your 'Answers to Correspondents' column on the following:—I am making a print washing machine with zinc; would it do to leave the zinc bare or should it be coated with something (the inner tray at least)? if so, what would be most suitable?"—In reply: Many washing machines are used with the bare metal, and when the zinc becomes coated with oxide it is scarcely likely to injure the prints, provided the major portion of the hypo is washed out prior to their immersion. The safest plan will be to cover the zinc with one or two coatings of Brunswick black. We ourselves never employ metal vessels for washing silver prints, as we much prefer porcelain or earthenware.

FOG writes: "Would you kindly, in your column 'Answers to Correspondents,' tell me the cause of the indistinct appearance of the image on the enclosed piece of Eastman's paper? It is enlarged from quarter-plate negative. I need hardly say that it has neither been properly washed or fixed, as it is the third I have made with similar results. The image came up slowly and refused to further develop. I have rigidly carried out instructions in regard to developer. I think it is not owing to fog from light in enlarging camera, which is a room made entirely dark excepting what passes through negative. The paper was fixed on carrier for holding it by means of ruby light."—Supposing the paper has not been exposed to extraneous light during its manipulation—and from the appearance of the print we have no reason to suppose it has—there is very little doubt but that the exposure has been far too short. Try the effect of at least three times the exposure.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, March 16, 1887, will be on *Outdoor Outfits*.

THE Seavill Manufacturing Company, New York, have favoured us with a richly-bound library edition of their *Times Annual*, which we have no hesitation in stating to be the most elegant volume connected with photography we have ever seen emanating from the New World.

A FRIEND sends us a newspaper cutting containing a very full account of the annual *soirée* and exhibition of the Glossop Dale Photographic Society. There are some things in it which we will take occasion to utilise shortly.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1402. VOL. XXXIV.—MARCH 18, 1887.

BACKGROUNDS.

A QUESTION which at the present time appears to be exercising the minds of many modern amateur photographers—if we may judge by the number of inquiries on the subject we have received of late—is, the best kind of background for portraiture to adopt in the coming season. The background of a picture is one of its most important features—a fact too often overlooked by photographers, though not so by painters. In connection with this subject, it is related of a celebrated artist that when a lady, anxious for her son to become a pupil of his, suggested that the lad might perhaps commence by painting the backgrounds, the famous artist replied to the following effect:—"Madam, if your son can paint my backgrounds he requires no instruction from me, for I find the background the most difficult part of the picture." However, it is not with the æsthetic part of the question we are now going to deal, but the practical.

Every photographer should possess at least one plain background, and with this, judiciously used, may be obtained far more artistic effects, and a greater variety of them, than is possible with the larger proportion of the scenic ones now in use. It must not be assumed by the uninitiated that because a background is a plain one it must necessarily appear of a flat, even tone in the photograph—this would be a fallacy. Those who are familiar with the portraits by the late Adam Salomon are fully aware of what can be accomplished, artistically, with plain backgrounds. The essentials of a plain background are that it should be of a flat and even tint. It should be free from creases and streaks, and possess a dead, or non-reflective, surface. Its colour, and the material of which it is composed, are of secondary importance, provided it has the proper photographic value to render the tint or tone required in the picture. The same background, it may be mentioned, can be made to appear either lighter or darker, according to the amount of light that falls upon it. We shall now briefly describe different kinds of plain backgrounds which have been, and now are, employed in portraiture.

The almost universal background of the amateur of old was an ordinary blanket. It answers fairly well, provided it be old and somewhat yellow in colour, otherwise it will prove too light for general purposes. Woollen backgrounds, of various tints, may be obtained at most photographic warehouses. These answer admirably, and are very convenient, as they can be folded up without becoming creased, but they harbour dust and are liable to be injured by moth.

A very useful background, particularly for groups, may be

formed by papering the end of the studio with plain paper, or a wooden frame may be covered with canvas and that papered. Plain paper, of almost any colour or shade, can be obtained from the manufacturers of paper hangings under the name of plain grounds. This is paper merely coloured with the ground colour before the pattern is printed. A background thus made is uniform in tint and very durable. It is also inexpensive. A piece of common brown paper forms a capital background, especially for vignettes, and is cheap. Suitable paper, under the name of carpet paper, about five feet wide and of any length, is supplied, at a few pence per yard, at all carpet warehouses.

One of the best backgrounds that a photographer can have, so far as durability is concerned, is one in flatted oil colour. If a background be simply painted with ordinary oil paint it will prove too glossy, hence the gloss has to be destroyed. There are different ways of accomplishing this. One plan which we have seen adopted is, to sift over some fine dry sand after the paint has been applied. This is absorbed by the wet paint, which then dries without gloss. Another way is, when the paint has just become tacky, to dust over the surface some flock—such as that used for wall papers—of the same colour. This plan answers well. The flock may be obtained from the dealers in artificial florists' materials.

The most general method of obtaining a dead surface on oil colour is by turpentine flattening, which is done as follows:—After the background has been coated with ordinary paint and become dry, it is gone over again with some of the same colour, but this time mixed with turpentine only. By this means the glossy character of the paint is destroyed and the surface left dead. It requires some small amount of skill to apply this coating without leaving the marks of the brush, particularly in hot weather, owing to the volatility of the turpentine. Hence, in flattening a background, it is usual for one person to apply the colour while another stipples over the surface with a large badger-hair brush. Another method of making an oil colour background is by what is known as soap flattening. This is common oil paint mixed with a strong, hot solution of soap. This when applied as ordinary paint dries with a dull surface. It is somewhat troublesome to prepare, but the novice is more likely to succeed with it than with the turpentine flattening just described.

Distemper backgrounds are easy to make, and are very generally used. In this case, the colouring matter is mixed with size and water, and applied with a common whitewash brush. These backgrounds are quite as good as those in oil,

except that they are far less durable. If a distemper background becomes wetted—as by a leaky roof—a stain, which of course will show in the picture, is produced. This cannot be got rid of without applying a fresh coat of distemper. Also the surface is easily injured by abrasion; a slight rub with any hard substance will produce a mark. If a background be coated many times with distemper, the accumulated colour is liable to crack, and, sometimes, to peel off. This never happens with a flatted oil one.

There is a very simple method of producing backgrounds which is well suited to the amateur, though it appears to be little known or seldom used. It consists in applying colour mixed with dextrine or similar material, as a dry powder to wet canvas, and then working it in with a brush. Backgrounds of this description are very durable, and are easily repaired should they happen to get injured either by water or by abrasion.

STAR PHOTOGRAPHY.

THE Conference of Astronomers arranged for Easter next for the purpose of discussing plans for a concerted system of photographing the whole of the starry heavens, will arouse so much attention, both among photographers and the public generally, that some account of what has been done already in this field of work will be interesting to the majority of our readers we do not doubt. We have on sundry occasions brought under our readers' notice the various wonderful achievements of modern photography in astronomical recording—representations of the solar surface and spectrum, lunar, cometary, eclipse, and transit photographs—all have excited vast attention, and we have kept our readers *au courant* with their leading details. Now, however, we would address ourselves to star photography only.

The project at present before the astronomical world is, briefly speaking, the division of the whole of the sky into a certain number of sections, each observatory devoting itself to one particular section, and, by degrees, obtaining a number of negatives embracing in the aggregate the whole of the allotted space. What is required is concerted action, and it is hoped that the Conference may devise a suitable plan for securing it.

As to the actual operation of photographing the stars, it is, primarily, simple enough, though the details are laborious. It is neither more nor less than treating the stars in the same way as a landscape, and exposing the plate to the image for a suitable length of time. The difficulty is twofold: first, a very long exposure is needed to obtain stars of small "magnitude," as it is termed—that is to say, of small apparent illumination—secondly, the objects, unlike a landscape, are continually moving away, or at least appearing to do; hence in a long exposure they are gone from the field of view long before the exposure is over. Astronomers, however, have instrumental arrangements worked by means of a clock so contrived as to turn a telescope that it shall always follow the moving object, and the astronomical camera is fixed to one of these arrangements. The clock is set going, the exposure started, and the plate follows the object, but, unfortunately, not with perfect accuracy. By means of a supplementary camera, or telescope, the observer can watch how the clock performs its duty, and by means of adjustments under manual control can render the following-motion perfectly uniform—that is to say, if he remain on the *qui vive*. When the exposure amounts to, say, three hours, our readers may imagine the state of exhaustion an observer, with his eye

fixed upon one star the whole of the time, must arrive at before the conclusion of his vigil.

The actual form the camera assumes is as varied as the optical means employed. This latter may be the ordinary astronomical telescope refractor, or a reflector, either with or without a magnifying lens at the focus; or, again, it may be an objective specially constructed or adapted for the purpose. Of the latter classes, by far the most celebrated instrument is the objective of Messrs. Paul and Prosper Henry, now in use at the Paris Observatory, where it was placed in May the year before last. The photographic lens is 33 centimetres in diameter, and 3.43 metres focus (*i.e.* about $\frac{1}{30}$), and it is accompanied with a finder of about the same focus, but smaller in diameter. This photographic lens has a chemical focus which is accurately determined, so often as once a month, by a simple process. The focus is first roughly found by means of a piece of blue glass, and then at measured small intervals on each side of this focus a series of images of a star is taken upon a small plate; the sharpest image shows the true focus, and the adjustment is made in accordance.

That such expensive optical appliances are, however, not actual necessities is proved by the work done by the Liverpool Astronomical Society, work, unfortunately, which has had to be given up, for a time, at any rate, through want of funds. They employed, and with conspicuous success, a camera and lens made by Mr. Howard Grubb, the lens being apparently a photographic portrait objective, as its focus is under sixteen inches and its diameter four and a half. This was mounted in the usual manner with a driving clock.

With both the Paris and the Liverpool instruments gelatine plates were, as we need scarcely say, employed. The Rev. Mr. Espin has given to the public his mode of working. He states that pyro development was tried, but soon given up in favour of ferrous oxalate; and to ensure the best action the solutions were made fresh for each evening. All the Liverpool negatives were taken on commercial plates, Wratten & Wainwright's "drop-shutter" plates being the brand employed.

At Paris the plates would appear to be made upon the establishment, as, in Admiral Mouchez's report in the *Annuaire* of the Bureau des Longitudes, reference is made to plates of various kinds, the most rapid being such as would not keep more than a day. These latter plates were, on that account, not employed in the actual work of mapping. The Admiral further states that there is a limit to the sensitiveness of the plates it is desirable to use, for, whether owing to light reflected from the lamps of Paris into the atmosphere, or from the rays of the moon, there is a certain amount of glare or diffused light which has an action upon the plates, and fogs them. *A priori*, it might have been thought the duration of exposure would have been diminished *pari passu*, and so obviated fog.

It will, no doubt, at once occur to our readers that some plan would be necessary to prevent small specks of dust or imperfections of the film being mistaken for stars, and this possibility has been felt and provided against, in a manner as successful as it is ingenious. The plan involves great labour, but the end is worth the means. Upon each plate the map of the stars is photographed three times over, by means of a delicate mechanical adjustment the plate being slightly shifted between each exposure in such a way that the image of every star is repeated so as to form a minute triangle. This triangle is so small that to the naked eye it appears as a single spot; but under a magnifying glass the three points are each seen, and thus error is rendered impossible. With regard to the

exposures required, there is a striking discrepancy between the Liverpool and the Paris experiences which is scarcely accounted for by the difference in the lenses. Thus, for stars of the fifth and sixth magnitudes, Mr. Espin gives one second and thirty respectively; while Admiral Mouchez requires only one-fiftieth and one-twentieth of a second for the same magnitudes.

We have, however, now treated with as much fulness as our space will allow the leading points of this most interesting subject, and we now leave it, hoping to return to it at no distant period with the object of showing how a little astronomical photography can be undertaken with no further apparatus than an ordinary portrait camera and lens.

COLOUR SENSITISING OR COLOURED SCREENS?

WE spoke last week of the possibility of discrepant results being obtained by different experimentalists with orthochromatic plates owing to slight variations in their methods of preparing or dipping the plates; and it is now our intention to say a few words upon some of the widely divergent opinions that have been expressed with regard to the value not only of home-made "colour-sensitive" plates, but also of the recognised brands of commercial manufacture.

We fully recognise that most probably these latter may, and no doubt do, vary materially from time to time, and that in consequence more or less divergent results may be secured by different operators; but it is scarcely just on this account to deny, as has been distinctly the case, the entire principle. Some time ago it was publicly stated by one gentleman that he believed orthochromatic photography to be a delusion; nevertheless, many others have convinced themselves, and what is more to the point, have supported their convictions in the most eloquent manner by actual results of a surprising character. Others, again, assert that the correct rendering of colour gradation is only a matter of exposure, and that ordinary plates, if properly treated, with or without the intervention of a coloured screen, will produce all the effects that are to be obtained by means of the so-called orthochromatic films.

We confess that we were at one time much of this opinion, but we cannot help acknowledging that experience has entirely changed our views; that, in fact, after commencing to experiment with the purpose of demonstrating this aspect of the question we were forced to recant, and now stand, in spite of the diversity of opinion and the numerous accounts of failures we hear, firm believers in the principle and its value. Perhaps the succeeding remarks on one or two points that have struck us may help in some cases to elucidate the mysteries of non-success.

The causes of failure, or supposed failure, may perhaps be generally classed under two heads; in the case of those who have attempted to prepare their own plates, the idea that all that is necessary is to *colour* the film, and with those who have failed with commercial plates, the expectation of too much has led to a want of recognition of what actually is gained. Without going into the theory of the process, it may be remarked that from what has recently been published it appears absolutely necessary that a silver compound must be formed with the colour sensitiser, while there is abundant testimony that mere colouring or staining the film is useless or worse. With regard to failures with commercial plates, it is possible, perhaps, that the makers are partly to blame in leading the public to expect too much; for when it is clearly stated that the plates may be used without the yellow screen the tyro naturally jumps to

the conclusion that the highest results are thus obtainable, and, finding such not to be the case, forthwith condemns the whole process. On the other hand, we do not agree with Mr. W. H. Hyslop, a successful amateur worker of orthochromatic plates, when he says that there are no plates in the market that will give an orthochromatic effect without a coloured screen. Our own experience is to the contrary effect, though we are not prepared to deny that there are plates in the market which absolutely require the screen, as the following experiments will show.

Two different brands of orthochromatic plates were pitted one against the other under precisely similar circumstances, together with another sample of ordinary (or shall we say, hetero-chromatic?) make, as a comparison. The colour chart employed comprised a variety of designs as well as colours, but the two combinations we shall have most pointedly to refer to consisted, one, of a bright but light yellow cross in a circle, the ground between the arms being filled in in alternate quarters in vermilion and bright, tolerably dark blue; the other consisted of a circle of the same yellow surrounded by a series of concentric lines in blue, separated by white.

The exposure required by the ordinary plate in order to give what we are accustomed to consider a "good" photographic result, was found to be five seconds. Exposures were then made upon each of the three samples of plates of five, ten, fifteen, and thirty seconds respectively, and each plate was developed separately in a solution of the same composition until the image appeared faintly at the back of the plate, where that was possible. The two samples of colour-sensitive plates, which we will call A and B, though they gave a perfect image with the shortest exposure, were evidently underdone, and it was not until A had had ten seconds and B fifteen that they could be considered fairly exposed. The ordinary plate with five, ten, and fifteen, gave negatives that would have been selected for quality in preference to all the rest; with thirty seconds it was overdone. As the result, so far as colour rendering is concerned, did not vary in the respective sets of plates in the slightest with the exposure, the only difference being in density and contrast, the sets will be compared as single plates presently.

Next we employed a coloured screen of orange-coloured silver stained glass; the colour was of considerable depth, but it was the lightest we had at hand. The plates A and B were then exposed for thirty seconds, one minute, and five minutes; the ordinary plate for one, five, and ten minutes. One minute sufficed for A and B, while five minutes gave a softer result without any general change in the character of the image; five minutes proved scarcely sufficient for the ordinary plate, but ten was all right.

Prints from these negatives are now before us, and we will as briefly as possible describe the different results. Taking the ordinary plate first, we have the yellow cross rendered midway between the blue and red, the latter being practically black and the former not much removed from white. The blue-margined circle is naturally rendered with a moderately dark body and lighter edge. The B orthochromatic plate gives precisely the same effects, differing not in the slightest degree in consequence of its colour treatment when used without the screen. The A plate has, however, shown a marked modification, though it does not go so far as the reversal of the renderings of blue and yellow. In the ordinary plate the yellow cross stands out perfectly distinct upon a parti-coloured ground, but in this its outline is lost, the yellow and the blue being rendered so nearly

alike that it requires close examination even of the negative to find the outline. In the other diagram, too, the two colours are reproduced with such nearly equal force that it is impossible to separate them.

Turning to the second series of exposures through the screen, the ordinary plate exhibits not the slightest variation from what we have already described in connection with the first sets. We may dismiss it at once. B and C, however, show an entirely different aspect. The first diagram represents a very light cross on an evenly dark—nearly black—ground, the blue and the red being perfectly indistinguishable even in the negative. The yellow circle, with its border of blue, which without the screen is shown as an evenly-coloured, rather dark ball, now appears as a very light disc, with a well-defined and much darker margin.

Another pattern in the chart consists of a series of alternate blue and green stripes, which are rendered without the screen upon both ordinary and orthochromatic plates, especially the former—with the blue much the darker; but in the orthochromatic plates, with the assistance of the screen, this result is reversed, showing that it is not only the blues and yellows that are affected, the green being reproduced in a much lighter shade with the screen.

These experiments, and numerous others of a similar nature, have convinced us, in the first place, that orthochromatic plates may possess a power of their own even in white light, but that it is greatly intensified by the use of the coloured screen; secondly, that plates may possess orthochromatic properties when aided by the screen, though they are totally devoid of them otherwise; and, thirdly, that the screen alone is of no use whatever with plates that do not possess some tendency in the direction of colour sensitiveness. We may qualify this by stating our belief that *some* plates may possess such tendency without having been specially prepared for colour purposes, though it will be in a greatly inferior degree. We are led to this view from an observation made in experimenting with the screen on a particular batch of plates, one of which, excessively under exposed, showed distinctly in the negative the well-marked cross on a clear, transparent ground. But even in this case, with a longer exposure, that sign of orthochromatism disappeared. These plates were of our own make, and contained chloride, which seems to lend itself to colour-sensitising purposes better than bromide.

We shall resume the subject next week, when we hope to have something to say further with regard to the theoretical side of the screen question.

Our readers everywhere, but more especially those in and around London, will learn with feelings akin to sorrow that a gentleman long and favourably known to them, either by name or personally—we allude to Mr. W. K. Burton—is about to leave this country for a protracted term of years. Mr. Burton has accepted an important position offered to him by the Japanese Government, and on the first of next month starts for his future home. He is to occupy the newly created "chair" of Sanitary Engineer in the Imperial Institute of Japan; and we are certain that we speak the sentiments of every one in wishing Professor Burton a prosperous career. He has promised that our readers will hear from him occasionally. Before leaving he will be entertained to dinner by a few friends. Those desirous of joining the party will find particulars in our issue of next week, as the details have not been settled at the time of our going to press.

TUESDAY last will long be remembered by residents in the Metropolis as a day of fog of a unique and exceptional character. Meteorologists

tells us that the cause of the combined snow and fog was that London was a kind of meeting-place of two streams of barometrical depression, the one coming from the east, the other from the west. But, be the cause what it may, the darkness at midday on Tuesday somewhat exceeded that experienced at midnight; it certainly was so around the Covent-garden district. It was not so much a genuine fog, as the term is understood, as a modified fog enhanced by a black pall overhead, which effectually debarred access of light from above. Professional photographers in London are, during winter and early spring, entitled to the commiseration of their brethren in the provinces. But even fog will not be without its uses if it prove an incentive to the more general introduction of the electric or magnesium light.

THE spontaneous discolouration of paper, always a subject of interest to the photographer, attracts at the present time more than usual attention, bound up as it is with questions of permanency. Many years ago it was shown that the so-called "fading" (a curiously contradictory expression) of certain carbon prints was simply the discolouration of the paper itself upon which they were printed, and every now and then the same point crops up when "permanency" questions are under discussion. It has always been considered that the presence of wood pulp in the composition of a paper is a material factor in the production of this effect, and experts could, no doubt, when thus forewarned, form a fairly accurate estimate as to the quality of any particular sample of paper in this regard. Hitherto, a ready test, simple in application, has not been described; but in a well-known German technical periodical Herr C. Wurster gives an account of a simple method of testing paper for the presence of such deleterious matter. He states that the yellow and brown colour acquired by some papers is due to the action of active oxygen on the resin used in sizing the paper, or, in some cases, upon the woody matter present in the paper; but that the presence, or even the percentage amount of woody matter can be determined by means of a test paper made of a certain chemical. When the moistened paper is pressed between paper containing wood, it acquires a deep red colour; ordinary sized paper merely turns it a delicate rose colour. Our readers, in the course of the eosine discussions, have been rendered familiar with the more than sesquipedalian names of complicated carbon compounds, and this new test paper has a name of equal lengthiness; it is made by steeping in a solution of dimethylparaphenylenediamine.

WE note that in the publishers' announcements for spring, photography promises to be well represented. Messrs. Sampson Low, Marston, & Co., announce the *Pioneers of the Alps*, to be illustrated by photographic portraits from the original plates taken by Captain Abney. Also *Life and Nature Studies* by a gentleman whose paper read before a metropolitan photographic society, given in our pages some little time ago, was read with such deep and absorbing interest by artistic photographers—Mr. Hume Nisbet. Then, again, Mr. H. K. Lewis will immediately issue *Photography of Bacteria*, illustrated with eighty-six photographs reproduced in autotype, by Dr. Edgar M. Crookshank.

Appropos of astronomical photography, we may draw attention to a note presented on the twenty-eighth ultimo to the Paris Academy of Sciences by M. Bouquet de la Grye, which will give some faint idea of the enormous amount of labour entailed after obtaining a desired set of negatives. M. de la Grye's remarks are upon the "Transit of Venus" results of 1882. Altogether one thousand and nineteen plates were dealt with, and the calculations involved were so lengthy as to cover no less than thirty-two thousand sheets of paper!

It is known that gas engineers are treading hard upon the heels of electricians in devising more powerful and cheaper gas lights (there is no doubt as to which is the more convenient process for photographers). Already there is to be seen in practical application in London a method of producing a powerful light by means of the heat

of a gas flame rendering incandescent an infusible body, and other similar systems are elsewhere in use; but at present the great drawback to this method is the cost of the gas. Water gas can be produced much more cheaply, but at present it is not, as a rule, "laid on." But an experiment is now in progress in Brussels which may have an important influence upon the price of gas. M. Wybauw, the gas engineer to the Municipality of that city, has advised the price of gas for day consumption, *i.e.*, for manufacturing purposes, to be reduced fifty per cent., and the plan has been in action long enough for him to be able to write that "The success of the experiment has been complete." That with gas at a shilling or eightpence per thousand feet there would soon be a practicable light for the studio, there can be little doubt.

THE LEGITIMACY OF DOUBLE PRINTING.

AFTER a careful perusal of the interesting lecture delivered by Mr. Norman Macbeth, R.S.A., before the members of the Photographic Club—and a careful perusal it richly deserves by all who aim at artistic work—one cannot but feel there is a bias and not in favour of photography in the assumption that photography is out of place if it attempts idealism. According to the lecturer photography has a plain matter-of-fact course to run, and it must not deviate from that track under any circumstances. This is scarcely fair to photographers, some of whom have succeeded in imparting by their own skill and intuitive perception of the beautiful, highly artistic and idealistic qualities to their pictures. Did not Rejlander produce anything that might fairly claim to be idealistic? Has not H. P. Robinson, Adam Diston, and others combined negatives so that the resulting print told its tale in a manner not to be gainsaid? And to my thinking a great deal better than scores of pictures we see hung at our picture exhibitions, and which claim to be exemplifications of fine art. Undoubtedly artistic improvement is the quality photographers will have to cultivate, and it is hard lines for them to be told at the outset they are seeking after a chimera, and the process they use is incapable of producing more than mechanical work at its best. Why the lecturer should set his face against a photographic picture being made of more than one negative I am at a loss to understand, unless he is under the impression it cannot be done without a great deal of hand work to hide the junction of the different negatives. This, at any rate is not the case, and a clever manipulator will be able to effect it without the slightest indication of such joins. That figures can be introduced into landscapes without infringing the least canon of art has been done repeatedly, and I do not think better instances of this can be pointed out than the small figure subjects with natural backgrounds Mr. T. Edge introduced many years ago. There was no touching up to hide the joins, and no inlaid appearance when they were done. They were perfectly natural, perfectly artistic, and perfect pictures in every sense of the word, and could the lecturer have seen some of the best examples I am inclined to think he would withdraw his opinion as to the inartistic effect of printing from several negatives.

Again, with respect to printing in skies to landscapes where otherwise there would be a blank space or a graduated tint utterly inappropriate for some subjects. Graduated tints only suggest a perfectly free, cloudless sky, and photographers aim at something more than only representing nature in its softest moods. Fancy a picture of a coast scene on a rough day, who would think a calm and cloudless sky could by any means accompany such a scene? It would be altogether out of place and an utter absurdity. Printing in clouds from a separate negative is, to my thinking, *when properly done*, a very artistic improvement, and I fail to see why any exception should be taken to it. Skies utterly inappropriate may be added, and frequently are, but that is no argument against their use in a *proper* manner; if they convey a truthful impression painters can do no more. It is said that because the landscape is affected by the shadows of the clouds that pass over it, by putting clouds in that were non-existent at the time is contrary to truth. Why this argument should be applied *only* to photographers is difficult to say. I should like to know how often a painter puts into his picture the sky that existed at the time he painted the landscape. The fact is that except in certain cases the shadows of the clouds are a very unimportant factor in the matter; in the first place

the cloud must be very dense, and, secondly, it must pass between the sun and the landscape being photographed. In a general way the sun is either at the side or behind the photographer, and the shadows east from the clouds are barely perceptible. If they do fall on the field of view the slight flattening effect produced is absorbed by local colour or configuration of the ground, and becomes quite inappreciable in the photograph. For clouds to visibly affect the photographic landscape they must be heavy, and the sun must be behind them and in front of the camera, and a wide open view must be the kind taken. Then with a very rapid exposure cloud shadows will be noticeable. Now, except for certain effects, such a position with the sun in front of the camera is rarely ever chosen, as it is the very worst kind of lighting for general subjects—opaque objects, such as trees, houses, &c., are rendered with little or no detail and in a manner silhouette against the sky, and the least mistiness in the atmosphere is greatly exaggerated. The cast shadows of clouds are so very indefinite and fleeting that few artists ever paint the same clouds that existed at the time they painted the landscape or the same shadow they produced—except, as I have already said, in special cases—and I am convinced that no artist or photographer could by any possible means decide if the clouds shown in the photographed picture existed at the time and were simultaneously taken with the landscape, or if they were entirely foreign to the subject. Of course this is presuming such clouds were artistically and skilfully managed. I have seen photographic pictures with skies taken simultaneously with the subject that had the appearance of being afterwards added, much more than when they were really so. It *very rarely* happens that the existing clouds compose anything like as well as clouds afterwards added, and the fact of the special suitability of the sky at once hints at double printing. Painters themselves generally suit the form of their clouds to their subjects, or ought to do so, and would probably be astonished if they were charged with not being true to nature because they did so. The fact is a certain amount of license is not only permissible but necessary in picture making, whether the means used are pigments or light itself. Any one taking advantage of the means at their disposal (by two or more negatives in the case of the photographer), so long as the results harmonise, are quite, in my opinion, within the legitimate scope of the art they employ.

EDWARD DUNMORE.

MECHANICAL OPTICAL LANTERNS.

LECTURERS are, no doubt, at times in great difficulty to find a suitable operator to work their optical lanterns and dissolving apparatus, and anything that can be made known in furtherance of the simplification of manipulation, or in the way of mechanical or automatic means of projecting pictures on a screen, must be of value to lanternists. If an audience is so fascinated by the subject matter and delivery of the lecture, and pictures are only required to demonstrate ideas or certain points in a lecture, a single optical lantern meets the requirement of the case, and with a little scheming a novice can be utilised to satisfactorily "second" the lecturer by passing in and out of the lantern the pictures to be produced; but, as a rule, if the entertainment is a pay one, something more for the money than ordinary photographs or pictures is looked for, and dissolving or mechanical effects have to be introduced to give variety.

Considerable ingenuity has been displayed in designing and constructing single and dissolving view lanterns and carriers to this end; and as some of them may have passed out of memory or not been heard of, I will endeavour to briefly describe those I consider to have merit and from which ideas may be borrowed or improved upon in constructing apparatus to meet the individual requirements of the lecturer.

In the front rank I think I must place a lantern which provides for the mechanical changing of the pictures by means of a rotating cube, holding in succession a series of photographs, fastened together by tape and passing out of one box into another through an open stage. The cube being just the size of the glass on which the view is photographed or painted, and hollow, as it is turned it moves away the picture last shown and brings the next one down, the tapes allowing the slides after use to fall flat into the empty box which is to receive them.

As I write this a plan suggests itself to me that I think could be utilised for optical lanterns, requiring but little attention while in use. It consists of an arrangement of wire holders for the slides, fastened to endless bands and turned by handles as in a revolving stereoscope.

In this way, if the condenser of the lantern is rather larger and of longer focus than usual, to counteract for the extra distance the photographs or pictures are away from it, a number can be shown in succession by simply turning the handle, and if holders for twenty-five are arranged for in height a double width would give fifty, and it would only be necessary to shift the box sideways after each twenty-five had been shown. Should more than fifty photographs be required to illustrate the lecture another box could be inserted, or it would be easy to arrange for sixty by making two rollers of thirty each. Either of the above plans have the merit of not requiring any more attention after once the light is started than the simple turning of a handle, and should the lecturer desire to be independent of any extraneous assistance whatever he could, without any considerable difficulty, get a simple pedal arrangement attached to the axis of the cube, or the handle of endless band, so that the foot, acting on a lever, the revolution could be performed.

Most oil lamps after being carefully adjusted require little attention during an hour and a half entertainment, and with the limelight, if the lecturer set all the taps carefully to get the best light and fixed one of the four-way Universal dissolving taps (or to express it more correctly, an on-and-off cock with bye-passes) between the jet and the bottle or ball and hydrogen supply, the light could be raised to its proper and originally fixed brilliancy, by simply moving the lever of the dissolver. The times, by means of clockwork, can be made to turn, and it must be a duncie indeed that with lime forceps handy could not replace a cracked or broken lime with a new one, after lowering the lights to the minimum to keep it alight, by moving the lever of the four-way dissolver.

It is a matter of surprise to me that these four-way dissolvers are not more used than they are for this purpose, as to my mind it is a great advantage after once getting the best light (and having everything ready) to be able to go away to the lecture table or elsewhere about the room, and know that on returning or giving a signal the impromptu assistant, with only five minutes previous tuition, can start operations by moving the lever. The gas bottle with automatic gas regulator attached furnishes a perfectly uniform flow of pressure after once being set.

For showing mechanical and ordinary slides as they may occur in the arrangement of the illustrations for the lecture, the lantern with double stage known as the "Metamorphoser" is an excellently designed instrument, and in its improved form capable of serving many purposes of a public lecturer if the operator has a little rehearsal and used ordinary common intelligence. The new Eclipse carrier designed and patented by Mr. R. Beard and sold by the leading opticians, makes the perfect centring of each slide certain and its change automatic, the only thing the operator has to do is to see that the slides are put in the carrier the right way up. If a bold label is put on the corner of each, showing the right side and proper way up, it is not likely a mistake can occur with a succession of photographs or pictures $3\frac{1}{2}$ inches high (the length may be $3\frac{1}{4}$, $3\frac{1}{2}$, or $3\frac{3}{4}$, and will still be centred). When a mechanical slide has to be shown the brass lever that shifts the stages is depressed and moves up into position the second stage in which the mechanical slide is placed.

The mechanical dissolving view apparatus I will describe in next article.

G. R. BAKER.

"ARTIST AND PHOTOGRAPHER."

How often I see this title (or, rather, these titles) in advertisements and on the back of mounts. Yet what a libel this is on photography! As the two words are separated by the conjunction it is left to be understood that *photography* is not *art*, but only that a photographer may also be an artist. If these advertisers mean "painter" by "artist," why don't they say so?

This introduces a question worthy of a few moments' consideration:—"Is Photography an Art?" I am perfectly aware that my readers are getting their "chestnut-bells" ready. I am ready to admit that the conundrum propounded above is a veritable worn-out "chestnut." But has the question ever been satisfactorily answered? I give below a few reasons why I answer "Yes" to the afore-mentioned conundrum.

First, its latitude. Any science or portion of a science becoming an art when one of its votaries can so weld it, by exercising his own judgment, into different form, that he can produce a better and more pleasing work than another who works, not by individual effort, but by rule.

* The operator has simply to insert the slide, push the runner right home, withdraw the runner and with it the slide last used, which he puts into a vacant box, and then repeats operation by inserting another slide. The act of drawing out the brass runner causes spring arms to automatically push the new photograph into position and consequently into focus.

Secondly, its indefinite formulæ. It must be an art when the successful working of much of its process is left *entirely* to the judgment of the worker.

Thirdly, the dictionary definition. The meaning of "art" is generally given as "skill; cunning; rules under the influence of practical skill." This last follows photography line for line. A. G. FIELD.

MR. MACBETH ON LEGITIMATE PHOTOGRAPHY.

It would be difficult, if indeed possible, to overestimate the value of Mr. Macbeth's utterances on the art side of photography; we can never have too much of such teaching. But I cannot quite follow Mr. Macbeth in his *dicta* as to what is legitimate and what is illegitimate in the art. Mr. Macbeth expresses himself with such admirable clearness that I, of course, understand precisely what he means, and while I sympathise fully with his views, I cannot fully agree with his arguments nor his conclusions.

Mr. Macbeth clearly argues that we are bound to confine our attention and our operations to what is purely and solely photographic action, the work of "simple reflection" as he puts it. I am not willing for a moment to deny that what is not light action is not photography, that would be a flat contradiction of terms on my part. But why should a photographer be confined to photography? Are we bound by any law to confine ourselves to the effects of "simple reflection?" In that case we must never trim our prints, nor mount nor frame them. Yet trimming, mounting, and framing, are important points in the production of artistic work. The painter draws as well as paints, yet I never heard painting called a bastard art. The sculptor is to a certain extent also a plasterer, but a statue is not an illegitimate production in common parlance. Why then should not a photographer be also a drawer, or a combiner, or an etcher? I cannot see where the difference comes in.

Mr. Macbeth sees no harm in getting together, all at one time and place, groups of figures with appropriate surroundings, but he will not hear of portions of the whole being photographed separately, and then combined by any means whatever. I grant the difficulty and the usual failure, but I ask, Where the objection? And why is a painter to be allowed to do what is forbidden to the photographer? Are we to insist that a historical subject is to be painted actually in presence of all the figures or models, and if not, why not? The one is as impossible to the painter as the other is to the photographer.

Mr. Macbeth objects to the double printing of clouds, and says it is more legitimate to wait till a suitable cloud comes on the scene than to select a suitable cloud from a box and print it in. Putting aside the question of *getting* the suitable cloud along with the view, and overlooking the somewhat nice point of *photographing* it along with the view, even with one of the old sky shades, I still cannot help thinking that the double printing operation is every bit as artistic as the other, and it is pretty certain to be more successful. Mr. Macbeth carries his aversion to double printing to a great height when he recommends as an alternative the ancient system of vignetting, or graduating the sky on the print. Nor can I see any vital difference between this vignetting and the vignetting of one negative into another, as in combination printing, which Mr. Macbeth deprecates. They are equally light action and equally vignetting, only the combination printing is *faute de mieux*, while the sky gradating is *faute de pis*.

And with regard to retouching. What good reason can be stated why we should be bound to leave portrait negatives with all their facial colour defects not only reproduced but exaggerated? Retouching is certainly not pure photography, but the virtues of charity, honesty, courage, are not pure photography either, and yet are not forbidden to the photographer. I remonstrate against the idea that photographers are to be forbidden all else besides photography. I thoroughly agree with Mr. Macbeth that retouching and combination printing are frequently badly executed; but that fact does not appear to me to condemn the operations, but only the operator in each particular case.

It is true that Mr. Macbeth does not pretend to urge any arguments in favour of his proposition, he merely states that he objects to certain things as being non-photographic. For my part I can see no reason for his proposition, and in certain phases Mr. Macbeth's reasoning seems to contradict itself, as I have already pointed out.

Is there a fear in some quarters that photography is encroaching, or apt to encroach, on the sacred precincts of painting? That is the only possible objection I can discover to combination printing and "modelling," and it is an objection entirely one sided and worthless from any point of view except one. I yield to no man in my veneration for a really good painter, but I have no great respect for a poor

one, and I consider a really good photographer a more admirable person than a second-rate painter. And I have a suspicion that the public is pretty much of my opinion in these latter days, when photographic portraits are being produced and carried (by the methods Mr. Macbeth objects to) to a pitch of beauty and excellence not until lately dreamed of. Photography will never probably affect the higher grades of painters, but it has seriously affected and will still more affect the less talented painters, unless, of course, photographers follow Mr. Macbeth's advice, and confine their attention to the mechanics and chemistry and the almost impossible combinations of figures and furniture which Mr. Macbeth seems to lay down as the fitting *ultima thule* of our aspirations.

Be it noted that I say nothing here of exhibitions. A photographic exhibition should be an exhibition of photographs, not of drawings, nor etchings, nor paintings.

Considering Mr. Macbeth's position, his experience, and his age, I deliberated carefully before thus venturing to dissent so strongly from his theories. But dissent I do most emphatically, come what may. If photography could be brought to such a state that we could by pure photography produce the effects we aim at, I should say, stick to pure photography. But at present it cannot be done, so I say, use what aids you can, no man has any right to forbid to you aids permitted to others. Photography, as well as painting, must be done so as to please.

ANDREW PRINGLE.

P.S.—I hope no one will suppose I am here advocating wholesale "retouching." I never tried to retouch myself, nor do I ever get my negatives retouched for my own use. "Modelling" at the best is a makeshift; but that does not condemn its use *in toto*. Better "model" than send out horrors.

A. P.

THERMO PHOTOGRAPHY.

I AM pleased to be able to give you the particulars of my experiments in the production of thermographic impressions on the solarised phosphorescent tablet, which prove the correctness of my first conclusions. The description which I append was communicated to the Franklin Institute at the last meeting, and the experiments have been repeated in the presence of Dr. Wahl, Secretary of the Institute, who can vouch for the care with which they were conducted.

I did not claim any discovery or advance in the production of negatives of the ordinary camera impressions on the phosphorescent tablet, but informed the members of the Institute that that was an old and practically useless, though interesting, method. I did believe I was the first to make any sort of a camera picture of an object by the action of the heat rays, never having heard of Captain Abney's lecture experiment which you mention. Even now I do not know what his method is, or whether he obtained anything more than a mere fugitive impression.

Referring to my reproduction of the limelight spectrum impression, it may be of interest to know that the spectrum apparatus was fitted with glass lenses, and the plate holder was about five feet away from the incandescent lime. The tablet was *strongly* solarised before exposure to the spectrum. With rock salt lenses, the heat spectrum would have appeared both longer and relatively stronger.

In regard to the "temporary exaltation and corresponding partial exhaustion of phosphorescence" which I observed, I find that Dr. Draper recognised this property of heat, he having stated, in 1851, that heat does not *destroy* phosphorescence, but *sets it free*. (Draper's *Scientific Memoirs*, pages 155-161.) Heat temporarily increases the intensity of phosphorescence, because it acts to liberate the phosphorescent energy.

A word, also, in regard to the indistinctness of "phosphorescent photographs." Sharp negatives cannot be obtained by contact, because the coating of phosphorescent powder must be made so thick that contact with the surface is far from being contact with the lower part of the layer, which also becomes luminous. But the phosphorescence itself does not spread so much as has been supposed. On suitably prepared tablets, camera impressions can be obtained that appear quite sharp, and reproduce in the camera much sharper than by "contact."

FRED. E. IVES.

HEAT PHOTOGRAPHY.*

At the November meeting of this Institute, I described certain experiments in photographing by the aid of the phosphorescent tablet, and announced the discovery of a means of photographing obscure objects by

* This term may be objected to, but is employed because the result of the method described is a fixed photograph of a fugitive thermographic impression.—F. E. I.

the action of heat radiations. Since then, I have made several camera photographs of metallic objects by the action of obscure heat rays, which I placed the objects in a position to reflect. With a source of heat produced with the consumption of coal gas, at the rate of only three feet per hour, I obtained strong heat photographs of small metallic objects, with camera exposures of only ten seconds. But, although a moderate amount of heat was sufficient to give such striking results, it proved to be necessary, under ordinary conditions, to employ heat of a certain quality or intensity, which can be obtained only when the source of heat is also a source of light. My source of heat was the incandescent lime of the oxyhydrogen light, placed in a dark box, one side of which was of black glass; the black glass transmits about thirty per cent. of the intense heat rays, but no rays capable of producing phosphorescence or of affecting bromide of silver.

The object was focussed by the light rays, allowance being made for difference of refrangibility of the heat rays; the light was then extinguished by the black glass, and a solarised phosphorescent tablet exposed in the camera. As I explained in my preliminary communication, this exposure produces a dark impression instead of the luminous impression that would be produced by violet light, and the photograph of this impression, made by contact printing on a photographic sensitive plate, is, therefore, a positive, instead of a negative.

I attempted to substitute a hot iron for the incandescent lime as a source of heat, and even to photograph the hot iron itself, but without success. This might seem to indicate that the tablet is not sufficiently sensitive to the feeble heat rays radiated by objects not heated to incandescence; but a simple experiment demonstrates that such is not the case. Contact with the hand for a single second will produce the characteristic sudden exaltation and partial exhaustion of phosphorescence in a tablet that has been kept at a sufficiently low temperature after solarisation, and a simple calculation will show that enough heat is radiated from the hot iron to produce, in a little while, a strong impression in a camera some feet away. The knowledge of this and of the fact that rock salt lenses transmit, and metallic mirrors reflect, these feeble heat rays, led me to hope that I might photograph obscure objects without having to secure the special conditions that now appear to be necessary. My failure with the hot iron proved to be due to absorption of the heat rays by aqueous vapour in the air. Professor Tyndal found by experiment that the aqueous vapour in the air of his laboratory absorbed seventy times as much heat as the air itself. My experiments were conducted in very damp weather, and nearly all of the heat radiated by the hot iron was evidently exhausted in warming the air, and was carried away in air currents. Although I did not accomplish what I hoped to in this direction, these experiments have made it evident that in a perfectly dry atmosphere it would be possible to obtain photographs of obscure objects by the action of heat rays of low intensity.

I have two illustrations of the method; one is a heat photograph of a German silver key check, the other a photograph of the impression produced on the solarised phosphorescent tablet by the limelight spectrum. The key check photograph is quite small, but reasonably distinct. I believe it is the first heat photograph of an object that has ever been exhibited. The shadows of three pins are reproduced in the spectrum photograph; one was in the violet of the spectrum, another in the yellow, and the third at the lower limit of the visible spectrum. This photograph proves what I have already asserted—that in Balmain's paint phosphorescence is produced chiefly by the violet rays, and the dark heat rays below the visible spectrum act most powerfully to exhaust that phosphorescence. Exposures on the solar spectrum gave substantially the same result, but showed relatively more action by luminous heat, and distinct but very feeble action in a portion of the ultra violet spectrum—the latter action was utterly insignificant as compared with the action of the same rays on bromide of silver.

In my preliminary communication I stated my belief that certain results that one M. Charles Zenger recently claimed to have obtained by the aid of Balmain's phosphorescent paint could not have been obtained in the manner that he described. My later experiments confirm this belief, and I would not again refer to Zenger's communication had it not been widely published, attracting much attention. Balmain's paint is but feebly sensitive to invisible chemical rays, glass lenses are practically opaque to all heat rays radiated by bodies not heated above 200° Fahr., and even a moist atmosphere will not transmit the feeble heat rays to any considerable distance. If Zenger obtained a photograph of a midnight landscape in exactly the manner he described, it must have been by the action of light rays that would have produced a much stronger and better photograph by acting directly upon the photographic sensitive plate itself.

One other statement of M. Zenger's calls for correction by me.

He asserts that collodion-bromide emulsion plates stained with chlorophyll are sensitive to all parts of the solar spectrum "from ultra violet to ultra red." More than seven years ago I discovered and published the fact that such plates are so remarkably sensitive to all colours as to be capable, with the aid of a weak yellow light filter, of producing correct colour tone photographs of all coloured objects; but it is not true that the sensitiveness extends to the ultra red rays: it stops abruptly at the Fraunhofer line α in the red, as shown by spectrum photographs that have been made on such plates.

HOW TO PRODUCE A NEGATIVE.

[A Communication to the Dorset Amateur Photographic Association.]

THOUGH a very elementary subject, it will not, I trust, be considered an inappropriate one for the first practical demonstration before a newly-formed amateur photographic society, particularly since one of the objects of the said society is to assist beginners in the art.

I have more than once heard lately the regret expressed that the days of the old wet plate for field work have passed. It was said that with a wet plate you knew what you had before you left the spot; with a dry plate you might discover when a hundred miles away, and it was too late to rectify an error, that your dry plate was over or under exposed, or that there was some defect in it. The use of the dry plate has its drawbacks, but they are trifling compared with those associated with the use of the wet plate process. Many years ago I worked the collodion process in the field, and I still retain a vivid recollection of its troubles. The wet plate photographer was encumbered with a cartload of material and *impedimenta*, which had to be loaded and unloaded at each operation—he had to work in the stuffiest of tents, generally in the most uncomfortable of attitudes, and in a temperature inside which in summer was more than tropical. After going perhaps miles, he might discover that a leak in his bath cover, or an accident to his collodion bottle, or an oversight, had rendered his journey useless, and he had to return without attempting a picture; in many cases the accident was one which could not have been foreseen. I remember an unfortunate accident of this nature which befell me some twenty-five years ago in Ireland, near Killarney, where I was photographing. A room in the lodge of the house where I was staying was assigned me for photographic purposes: there I bestowed my goods and was happy. A convenient cupboard received my solutions and chemicals, and preserved them from curious and prying eyes and restless fingers; but not altogether, for one day, on going to the cupboard for the nitrate of silver solution for the bath, to my consternation the bottle was half empty. How could I replenish the bath nine miles from anywhere, and what should I do in the meantime? I feared the maid who looked after the room might have mistaken the clear solution for the “craythur” and drank it. My fears were allayed by hearing no allusion to the matter and seeing the girl in her usual health; but the bath had gone, and the maid alone had access to the room, and I could only suspect Bridget, who was accordingly sent for and questioned as to what had become of the liquid, and charged with having made away with it. This she indignantly denied. “Would she be ather a-going to the masher’s cupboard?” It was not herself who would be doing such a thing, at all at all!

There was no help for it—the bath was gone, and there was no photography to be done until fresh chemicals could be procured from England; and the worst of it was the criminal could not be traced, and might next empty the collodion bottle. Next day Bridget’s face began to assume a darker hue in streaks and patches, which became black and blacker. Bridget was terribly alarmed when she saw herself in the glass. She washed the stains with soap and water to no purpose; she scrubbed it with the scrubbing-brush, it still grew darker; pumice-stone and sand were tried—they removed the skin but the patches became more and more marked. Bridget was superstitious—the marks must be the marks of the “devil,” and she flew to the holy water which the priest had specially blessed for her; but even the holy water had no effect upon it. What would become of her, with the marks of the beast so evidently upon her? Bridget was then reminded of the cupboard and advised to confess all she knew about it, and the truth came out. She was dusting the room, and with a woman’s curiosity had gone to the cupboard to see what it contained; the clear liquid in the bottle tempted her, she would draw the cork, but as the cork was not easy to draw she applied more force—the cork yielded suddenly, so suddenly, that much of the contents was spilled on the floor. Shocked at what she had done, she hastily put back the bottle, and with her duster wiped up the clear liquid from the floor; the day was warm, she became hot with the exertion and with the fear of detection, and she wiped her face with the duster! It was a fortnight at least before Bridget was restored to her normal condition, and I think she never went to that cupboard again; she did not at least whilst I was there.

This little story, which is strictly true and unvarnished, has its moral. The moral is this:—There is something worse than not being sure whether you have a picture or not upon your plate, and that is, not being able to attempt a photograph at all.

I trust there is no doubt about the pictures upon these plates, or there will be no demonstration of development this evening. It is not a difficult matter in the summer, with a reliable plate and on a fine day, to secure twelve good views on twelve plates exposed consecutively, but at this time of the year the case is different; with the dull, uncertain light of these short days, which varies almost every ten minutes, one cannot be certain that the right exposure has been given. Let us try. The plate is one of Miall’s make; he is a good maker of a cheap and reliable plate. I have tried his plates by the side of some of the best in the market, and I have found them equal in every respect to any I have tried. I buy them by the gross, and I take care to stipulate that the whole batch shall be of one emulsion. After developing one or two trial plates I can determine for the whole what exposure or modification of treatment they require.

The first step towards taking the photograph is the *choice of the subject*. There are plenty of men who can take a picture which is technically perfect, but it requires the artistic taste and the artistic talent—which is innate and not acquired—to compose a picture. The photographer here is at a disadvantage as compared with the artist. The latter can leave out or modify any object which is not in harmony with the main subject, or which mars the repose or composition of the picture. The photographer must take all that comes into the field of his lens. Again, many pictures which look well to the eye will not compose well when seen on the screen, and in other respects much experience and dodging may be required to secure an artistic picture. Still, something may be learned from books, and much for the education of a latent artistic taste; but as the subject is a wide one to enter into here, I may perhaps be allowed to refer you to Mr. Robinson’s well-known books for many useful hints and much valuable information on artistic photography.

Having chosen your subject, the next thing is to *focus it*. If your subject is not a general one you would focus on the object of principal interest. For instance, you are taking a view of an old ruin. Remove the stops from your lens, and rack in or out the movable part of your camera until the principal details of the ruin in the centre of the picture are as sharp as you can make them; then stop down until the whole ruin is as sharp as you require it. If your subject is a general one, focus upon some object in the middle distance. A word may be said here about lenses, and especially about cheap single lenses, which it is a fashion to run down. Of course, if money is a matter of little consideration, and you want the best all-round lens, there is nothing to beat a Dallmeyer’s rapid rectilinear, but that first-class artistic work can be readily produced by cheap single lenses of the *modern type* is undoubted. I have here, and I hand round for examination, some photographs; they are not my own work, and I can accordingly speak more freely in their praise than I could otherwise have done. Two of them, you will observe, are figure subjects; another is an interior, with a figure sitting beneath an arcade of arches in an Italian painter’s studio; the fourth is the interior of an Italian kitchen—all of them subjects which are generally admitted to be most trying for a single lens. They were taken by an American lady with a cheap camera and a cheap single lens. What could be more artistic than the groups? And observe the softness of the interior of the Italian kitchen, with its shapely utensils lying about, and specially note the straightness of the perpendicular and horizontal lines; the lines, even that trying one of the corner of the room on the edge of the plate, are, so far as the eye can detect, perfectly rectilinear and perpendicular.

We have our subject focussed; what exposure shall be given? I have met amateurs and professionals whose views on this point are a little unsound. Sunlight, I have been told, is sunlight; and if you are taking a picture in brilliant sunlight at midday, whether in June or December, the exposure should be the same. You, gentlemen, know better than that, but you may not have considered the reason why this is not the case, why the sunlight of June is so much more actinic than the sunlight in December. I have here a diagram which will make it evident. The

meridian altitude of the sun on June 21 is $62^{\circ} 30'$, and on December 21 the altitude of the sun is $15^{\circ} 30'$. C D E F represents the surface of the ground, A represents the sunlight, which passes through a cardboard screen with a hole cut in it one foot square, and set at right angles to the source of light (the sun) on the 21st of June, midday—the light forms a rectangle on the ground of which C D represents the side. B represents the sunlight which passes through the same screen on December 21; it covers a rectangle of which C E is the side. C E, you will observe, is more than three times the length of C D, or, in other words, the same amount of sunlight which falls upon the surface of the earth on June 21 is distributed over three or four times the area on December 21, midday.*

How many seconds shall we give? Can you count *seconds* accurately? This is an important matter, for until you can do so it will not be possible for you to compare your exposures or the speed of your lenses with others. You will find a piece of string useful for learning to count seconds. Put a small bullet at the end, or your knife may be tied temporarily; tie a knot in the string about thirty-six inches from the weight, hold the string by the knot—you have now a pendulum, which, whether it swings slowly or fast, whether it swings through a greater or smaller arc, will always swing seconds. Your string and weight will be useful for another purpose, namely, to set your swing back perpendicular when photographing architectural subjects. Set your camera to take in the subject you desire, adjust the swing back by the weighted string held beside it, and focus.

We have chosen the view, focussed and exposed it, the next thing is the development. What *developer* shall we use? Ammonia and pyro, ferrous oxalate, carbonate of potash, soda, or some combination with

* The engraver has not given the angles accurately in the diagram, the length of the lines C D and C E do not therefore bear the proper relations to each other.

sulphite of soda, sulphurous acid, citric acid, or one of the more recent novelties? Until the amateur can produce good negatives with the old stock formula of pyro and ammonia he should not attempt any other; the plates which will not stand the ammonia developer, and the amateur who cannot use it, are neither of them of much account. When he has become tolerably expert with the ammonia, he might try experiments with other developers; but I think he will, in the end, go back to dry pyro and ammonia as being, on the whole, the best and most reliable for general use.

The solution of pyro preserved by the addition of sulphite of soda and similar chemicals is not altogether suited to the use of the amateur who only takes photographs occasionally. I have found much difficulty in obtaining it pure. Much of the commercial sulphite appears to be contaminated with foreign substances, which affect its action, and if pure, however carefully it is corked, it appears after a time to attract oxygen from the air, which converts it into the sulphate which retards the action of the developer, and it is open to question whether a similar change does not take place in it when it is kept for any length of time in solution, so that its properties become altered. The addition of sulphurous acid, as in Beach's formula, would, however, help to preserve it.

I formerly had much faith in citric acid added to the developer in the proportion of one-eighth to one-fourth of a grain to each grain of pyro, and for some purposes I still regard it as invaluable, but there is the same difficulty in obtaining it pure; it is commonly adulterated with more or less of tartaric acid, which ruins it for the purpose for which it would be useful if pure. I now obtain pure citric acid from a good chemist. When added to the developer in the proportion given above it makes a slow but admirable developer for transparencies on ordinary bromide plates. The deposit is slow, but exceedingly fine. A lantern slide developed by means of it will be clean and of good colour, without toning; try it for this and for transparencies for enlargements. For the latter purpose especially you will not be disappointed with it, though you may prefer the ferrous oxalate. You must remember, however, that with citric acid in the developer you will require much more ammonia.

But let us proceed with the development of the plate. We have in this wide-mouthed bottle little packets of pyrogallie acid folded up in tissue-paper, each packet twenty-four grains of dry pyro; in this form the pyro will keep almost indefinitely, though the wrappers may become discoloured. One of these packets contains sufficient pyro to develop four half-plates or a corresponding number of whole or quarter-plates. We have two half-plates to develop. We open a packet and divide the contents roughly with a pocket knife in half; the half we place in this eight-ounce measure, and add water up to the four-ounce division. We pour two ounces of the solution (which, you will remember, contains six grains of pyro, three to the ounce) into this developing glass, and having placed the plate in the tray, we pour the solution of pyro upon it thus. You will observe there is a thread beneath the plate—the ends of it are joined underneath the tray; by means of this the plate can be raised for examination very readily, and without soiling the fingers. Some persons soak the plate in water before developing. I have never been able to understand what advantage is gained by soaking the plate and filling the pores of the film with water, when it is as easy to fill them with the solution of pyro, which will assist development and help to give vigour to the negative. We will leave it in the solution of pyro for two minutes or so, meanwhile we will drop into the developing glass three or four drops from this stoppered bottle, which contains to each ounce of water—

Bromide of ammonium 30 grains.
Liquid ammonia ('880) $\frac{1}{2}$ ounce.

We pour back the solution of pyro from the tray into the developing glass; this mixes the bromide and ammonia thoroughly with the pyro solution, which we now return again to the tray. We will now gently rock the tray, that the development may proceed evenly and regularly. The image is appearing, you will observe, in the high lights; they are now well marked. We will pour six or eight more drops from the stoppered bottle into the developing glass, and proceed as before. The development is complete. Notice the density of the high lights when viewed by transmitted light, and compare mentally when you see the picture in its finished state; it will be a guide in future development. We will now wash the plate under the tap, and place it in this tray, which contains a saturated solution of alum. It may remain there whilst we develop the second plate. That being done, we remove it from the alum, wash again, and place it in this solution of hypo, which has been used over and over again. I prefer a glass dipping bath similar to those used for the nitrate bath in the old collodion process, as the particles of silver salts fall to the bottom, and do not adhere to the films and cause spots, as they are apt to do when the plate is placed in the tray film upwards.

Observe, the plate is clearing, the free silver salts not acted on by light are being gradually dissolved out by the hypo. We must not, however, trust to this old hypo bath. We will take the plate out and immerse it for five minutes or so in this fresh solution of hypo, five ounces to the pint. The negative is now finished. It remains only to wash it well in several changes of water; if we had water laid on it would be well to leave it for a couple of hours under the running water. When thoroughly dry it will be varnished with enamel collodion or negative varnish; but the latter does not afford the same protection to the gelatine plate as it

does to the collodion negative. I will pass round these negatives and will send prints from them for the next circulation, you will then form your own opinion about them.

W. MILES BARNES.

ON SHUTTER EXPOSURES FOR OBJECTS IN MOTION.

In photographing a moving object, the resulting picture will always be more or less blurred. All that can be accomplished is to reduce the blur within such limits that the picture will appear sharp to persons viewing it. This limit, it is obvious, varies with the requirements of each picture. For smaller pictures this limit may not exceed four one-thousandths of an inch, when for larger pictures, to be viewed at a distance, one-hundredth of an inch or more may be admissible.

To reduce the blur, two methods are usually employed—either to increase the distance at which the photograph is taken, or to increase the speed of the shutter. The first method is limited by the size of the picture required, the second method by the sensitiveness of the plate used.

To obtain a desirable sharp picture, we have to select the proper distance at which to photograph the object, and adjust the proper time of exposure (speed of shutter).

The following formula will show the relation that exists between velocity of motion, distance, focal length of lens, time of exposure, and admissible blur:—

If D = distance of object from optical centre of lens, in feet;

M = velocity of object, in miles (statute), per hour;

F = velocity of object, in feet, per second;

f = equivalent focal length of lens, in inches;

S = time of exposure, in seconds;

l = limit of blur, in inches;

$$\text{Then, } D = \frac{44}{30} \cdot \frac{f}{l} \cdot MS + \frac{f}{12} = \frac{f}{l} \cdot FS + \frac{f}{12}.$$

In these equations, of which one is used when the velocity of the object is given in miles per hour, the other for velocity in feet per second, the term $\frac{f}{12}$ may be omitted, as in comparison with the distance D it will be found so small that it may be neglected, especially as the distance will nearly always be estimated.

From the above formula we can derive others, in case we desire to find the speed of shutter, the distance being given, or in case we desire to construct a table for exposure, in which the ratio between distance and focal length of lens is used as argument, namely:—

$$S = \frac{40}{30} \cdot \frac{Dl}{Mf} - \frac{1}{17.6} \cdot \frac{l}{M} = \frac{Dl}{Ff} - \frac{l}{12F}.$$

$$\frac{D}{f} = \frac{44}{30} \cdot \frac{MS}{l} + \frac{1}{12} = \frac{FS}{l} + \frac{1}{12}.$$

A table is here given of distances in feet at which an object in motion has to be photographed in order to obtain a sharp picture, the equivalent focus of the lens being six inches, the rapidity of shutter $\frac{1}{1000}$ th of a second, and the blur being limited to $\frac{1}{1000}$ ths of an inch:—

Velocity, miles, per hour.	Distance in feet.	Velocity, miles, per hour.	Distance in feet.	Velocity, miles, per hour.	Distance in feet.
1	44	11	481	10	440
2	88	12	528	20	880
3	132	13	572	30	1320
4	176	14	616	40	1760
5	220	15	660	50	2200
6	264	16	704	60	2640
7	308	17	748	70	3080
8	352	18	792	80	3520
9	440	19	836	90	3960
				100	4400

For lenses of f' focal length, multiply the value of D in the table with $\frac{f'}{6}$. For different value of l say l' , multiply similarly with $\frac{4}{1000l'}$. For different time of exposure, S' , multiply the table value of D with $50 S'$.

USE OF ABOVE TABLE.

Having an outfit of above description, that is, a camera with a lens of 6-inch E. F., and a shutter of a speed of $\frac{1}{1000}$ th of a second (nearly all shutters will have that speed), it is desired to take a ship sailing 13 miles an hour. In the above table we find opposite velocity 13 miles per hour, the distance of 572 feet, the nearest distance at which we can obtain a sharp picture.

If we can find the velocity in the above table the distance required will be opposite that velocity.

Should the velocity not be found in the table, as for example a velocity of 26 miles per hour, then we enter the table with 20 miles per hour, which gives 880 feet. Next we find velocity 6 miles per hour, which

gives 264 feet. Adding these two gives us for 26 miles 1144 feet as the distance required.

But if our outfit should have a lens of equivalent focal length of $6\frac{3}{4}$ inches instead of 6 inches, then in the above example we multiply 1144 feet with $\frac{6\frac{3}{4}}{6} = \frac{27}{24}$, which gives 1287 feet.

Suppose, again, your shutter should only have a speed of $\frac{1}{100}$ th of a second, then we multiply 1144 with $50 \times \frac{1}{100} = \frac{1}{2}$, which gives us the distance of 1430 feet with 6-inch lens, and with $6\frac{3}{4}$ -inch lens we multiply 1287 with $\frac{1}{2}$, which gives us the required distance of 1609 feet nearly.

Should in this last case a blur of $\frac{1}{100}$ th of an inch be admissible, we multiply 1609 with $\frac{1}{100} \div \frac{1}{100} = \frac{1}{100}$, which gives the distance of 644 feet nearly.

In estimating velocities some very plain points must not be forgotten. If we are on board of a steamer moving at the rate of 14 miles per hour, and we wish to take a boat sailing at the rate of 12 miles an hour, when passing abreast we have a velocity of 26 miles an hour for the object; should we overhaul a boat sailing at that rate we have only a velocity of 2 miles per hour for the object.

A railroad train running 40 miles an hour, if taken at a distance of 1760 feet, will not show a sharp picture for some parts, such as top of the wheels, &c., as they move at a much faster rate, the top of the wheels requiring 3520 feet distance to be sharp.

Similarly the feet of men and animals move faster than the body.

Again, moving objects taken at an angle which is not a right angle with the line of its motion, will admit of a longer exposure without increase of blur. The more this angle differs from a right angle, the more may the exposure be prolonged.

A. HEGER.

—*Photographic Times*.

A CURIOUS PHENOMENON IN DEVELOPING.

SOME time ago, while the Editors of the *Bulletin* were working together in the dark room, and developing some rapid exposures, they noticed that on removing the plate from the developer and after slight washing, that on immersion in an alum solution the whole surface of the plate glowed with a phosphorescent light. As the phenomenon was a little startling, the effect was looked for and noted at the same period in the course of the making of each negative. It was then suggested that it would be a good idea to endeavour to ascertain the origin of the phenomenon. For this purpose some developer was mixed with the alum solution in the dark, but no phosphorescence was noted. The above operation was then reversed, and, after a number of experiments, it was found that when the developer is sufficiently weak, on pouring into it some strong alum solution, the phosphorescent light appears at the moment of mixing. This was as far as we went with our experiments, intending to return to the matter at some future date. But quite recently we see that others have noted the same phenomenon and various theories have been suggested to account for it.

At a recent meeting of the Société Française de Photographie, M. Perrot de Chaumeux, of Prissac, Département Indre, remarked that he had noted a phosphorescent light which appeared upon the surface of rapid plates on removal from the developer and immersion in a saturated alum solution. In this case the development was with separate solutions of pyrogallol and sodium carbonate according to the method of M. Audra, the pyrogallol having nitric acid in it instead of sulphuric; the plate being placed in them in the order given above, first pyrogallol then sodium carbonate. M. de Chaumeux states that the phosphorescence was not only upon the immersed plate, but also in the adjacent solution. At the same meeting, M. Pector said he had noted the same effect in using Balagny's pellicles at the moment of detaching from their supports, and another member, M. Londe, stated that he had observed the same light on developing the Balagny pellicles. M. Molteni said that phosphorescence was also produced upon developing gelatino-bromide plates in an acid pyrogallol bath; while M. Stebbing said that cutting gelatino-bromide plates with a diamond produced a like result. The general impression appeared to be that the phenomenon is electrical.

Since the above observations were published, we note that English photographers have observed the same phosphorescent light during development. Among these observers we note Mr. John Daniell, of Llanelly. This latter experimenter does not think the phenomenon an electrical one, and we agree with him. Water and saline solutions are too good conductors of electricity to admit of luminous electric discharges in them. We believe that the effect is due to chemical action only, and is probably a combination of the pyrogallol with the alum. The fact that we produced the effect without using a plate in the developer, shows that it is an action due to chemical changes between the chemicals independent of the plate or silver haloids. The kind of developer used does not appear to make much difference, M. de Chaumeux used soda, while we used mixed soda and potash, and Mr. Daniell used potash as the alkali.

The observations of MM. Pector and Stebbing are of an entirely different character. The separation of the Balagny film from its support, and the cutting of the plate with a diamond are both capable of producing electrical phenomena. It is well known that the splitting of crystals of certain minerals produces electric phosphorescence at the moment of rupture, and the separation of the Balagny films is another phase of the same

action, while the cutting of the plate with a diamond is purely friction, and we all know that produces electrical charges.

But no matter what the origin of this phosphorescent light, we think it is important to prevent its appearance during development. There can be no doubt that light of that character immediately upon the surface of the plate will produce fog. The plate is in an extremely sensitive condition, and any light not purely non-actinic would affect it. The method of prevention is a very simple one, and is to wash the plate pretty thoroughly before immersion in the alum bath. By this procedure all risk of fogging the plate from phosphorescent light is overcome.

If any of our readers have noted this phosphorescence during development and can add anything to the observations we have mentioned above, we shall be glad to hear from them, as the subject is undoubtedly a very important one in photographic practice.

—*Anthony's Photographic Bulletin*.

REVIEW OF EXHIBITION OF LANTERN SLIDES BY AMATEUR PHOTOGRAPHERS OF CINCINNATI.

THE Ex-Cincinnati Camera Club, now the Photographic Section of the Society of Natural History, gave on January 19 their fourth annual exhibition of lantern slides at the Odeon, before a brilliant audience of about fifteen hundred people, mostly friends of the members of the Club.

The pictures were projected on a screen about twenty-four feet square, by means of two oxyhydrogen lanterns.

Out of a membership of fifty-two, twenty-one members contributed about two hundred slides, from which one hundred and twenty-five were shown. A number of the amateurs being tourists, the geographical variety was quite extensive, and while covering most of the United States, also included glimpses of the Old World. By a judicious management on the part of the Exhibition Committee, the slides were divided into different classes.

Only one entry in statuary is made. Mr. Bullock giving us a perfect image of the Bartholdi Statue.

Reviewing the Exhibition in a general way, it was a meritorious display of lantern slides. Technically they compared favourably with slides exhibited by professionals, while the subjects were more original.

Perhaps the most interesting class of subjects was that of "Compositions," original or otherwise. It is natural that it should be so, since a composition calls upon our artistic faculties for successful production. Characteristic and ideal subjects will generally be more appreciated. Landscapes of which there must always be a large proportion could be improved materially and become more interesting by the addition of clouds, natural or artificial.

As we are striving to improve as we go, perhaps no one will object to the suggestion. More clouds, more coloured slides, more original compositions.

L. M. PETITDIDIER.

Our Editorial Table.

HART'S NEW NEGATIVE WASHING TANK.

MR. F. W. HART, Kingsland-green, has brought out a negative washing trough of a useful type. In the outer vessel there is an inner one in which the plates are inserted in grooves set at an angle, so as to keep the plates in a sloping position, faces downwards. The water is admitted from the top and flows downwards through the plates under such circumstances that when the jets dash against the upper ends of the backs of the plates, the water rebounds from each back to the face of the one in the adjoining groove and passes downward in a species of zig-zag fashion, which removes the hyposulphite very quickly and effectively from the film. The water is withdrawn from the bottom under such circumstances as to ensure the plates being always left well underneath the water even when the supply is stopped. It is a well made and useful appliance.

THREE WEEKS IN NORFOLK.

London: Wyman & Sons.

THIS little work, by J. F. Mostyn Clarke, with illustrations from pictures by Edward H. Fahey, R.I., gives a description of an "outing" by the author and a friend towards the close of last summer on board the yacht *Rorer*. The place selected was Norfolk, the country of the "Broads," many of which streams were visited. The various adventures are most pleasantly narrated, and engender a feeling akin to envy of those who had it in their power to leave the dust and heat of the city to enjoy yacht life under circumstances so pleasant as those experienced.

The work contains numerous illustrations printed from Meisenbach blocks obtained from original negatives by the author and from drawings by Mr. Fahey. These afford a very good idea of the Norfolk Broads. It of course "goes without saying" that a clever

photographer like Mr. Clarke had his camera in active requisition during the pleasant three weeks of yacht life here described.

FALLOWFIELD'S NEW CATALOGUE.

MR. JONATHAN FALLOWFIELD, of 35 and 36, Lower Marsh, and 86, Oakley-street, Lambeth, S.E., has just issued a Special Season's Catalogue, a copy of which he has sent us. It is a very comprehensive and compendious one and embraces everything that a photographer can possibly desire. Lenses of all the recognised makers; cameras and stands of every form and for both studio and outdoor work; shutters innumerable; roll holders of various makes, and negative paper for the same; dark-room lanterns, burnishers, mounts, and dry plates in almost appalling variety—these and many other things, including optical lanterns and their appliances, all find a place in the new catalogue of Mr. Fallowfield.

ISOCROMATIC PLATES.

WE have tried some isochromatic plates sent to us by Mr. B. J. Edwards. In order to test them effectively, we employed a card containing a device in what are, *visually*, strongly contrasting colours, a very dark blue cross on a bright lemon ground. These are so carefully balanced as to give with ordinary wet collodion scarcely a trace of an image at all, and such we found to be the case. With the isochromatic plates the image was well marked, and this in a degree exceptionally so when we interposed behind the lens a piece of glass of a very delicate yellow colour, under which circumstances we obtained a vigorous dark cross on a light ground. This attests the value of isochromatic plates.

Department for Experienced Photographers.

SILVER PRINTING ON PLAIN PAPER.

WHILE we quite admit that there is a great charm in a photographic print having a surface as smooth and glossy as glass itself, yet equally so is there a peculiar charm in one totally devoid of all glaze.

Regarding the former, as we have prepared practical instructions for effecting the end in the most perfect manner, we shall say nothing concerning it here.

It will have been inferred from the previous article on this subject, that silver printing may be effected on plain paper quite as well as on that which has been albumenised. We have seen many excellent photographs made upon ordinary writing paper.

If any reader thinks of trying his hand at such practice, he must select a smooth, hard-sized wove, not laid, sample of paper.

This is to be salted by sponging or brushing it over with a solution of chloride of sodium (common salt), six grains to the ounce of water, and then suspending it to dry. But a much richer effect is obtained by the addition of three grains of gelatine, which imparts vigour to the print by keeping it more on the surface without imparting a glaze like albumen. Instead of brushing the solution over, it is much better to pour it into a flat dish and allow the paper to float on it for a minute. When dry it will remain good for a long time.

To sensitise the paper, float it for two minutes upon a bath of ammonio-nitrate of silver, made by dissolving fifty grains of nitrate of silver in an ounce of water (or in a larger quantity, adopting the same proportion), and then adding to it strong ammonia drop by drop. The effect of this addition is to cause a dirty-looking dark brown precipitate to be formed in the previously clear liquid, and the ammonia must be slowly added until indications appear that the liquid is beginning to become clear. Now stop and shake or stir the solution to mix the ammonia with it, when if not yet clear add more, but only by a single drop at a time, followed by stirring or shaking after each drop. Cease adding ammonia after the solution has become *almost* clear, for it is better that this stage be not quite reached than that there be an excess of ammonia. If the mark should have been overshot, a little more solution of nitrate of silver must be added.

This solution, when filtered, forms an exciting solution for plain paper which yields prints of great beauty of tone. It is not so well suited for albumenised paper. But for plain salted paper, while the above-described ammonio-nitrate of silver bath is undoubtedly the best, yet will a plain nitrate of silver solution also answer well, although, so far as our experience goes, it will not give such rich, deep chocolate blacks as the other.

The paper having been dried is ready for exposure.

Concerning the toning and fixing, this may either be done in the way described in a previous chapter on this subject, or, to save trouble, both these operations may be merged into one. To this end the printing should be carried till the image is nearly veiled in obscurity, and the

pictures, after being rinsed in plain water, immersed in a bath prepared according to the following directions:

In four ounces of water dissolve one ounce of hyposulphite of soda, fifty grains of sulphocyanide of ammonium, and thirty grains of phosphate of soda. After these have been dissolved, add to it two grains of chloride of gold previously dissolved in a little (say, two or three drachms) water.

The toning and fixing go on simultaneously, and the prints are allowed to remain in this until they have acquired a very rich black tone, by which time the effect of the over printing will have been obviated by a corresponding reduction.

After removal from the toning and fixing bath, the prints must be well washed.

The solution will remain good for a considerable period by strengthening it occasionally with a few drops of gold solution and the addition of fresh hyposulphite of soda solution. When it is considered to be quite used up by long keeping or frequent use, it may be poured into a convenient bottle of large dimensions, or jar, in which other waste hyposulphite solutions are kept, for by a simple chemical treatment hereafter to be described, at least two-thirds of the silver employed in the sensitising of the paper can be recovered, thus reducing to a material extent the expenses incurred in riding the photographic hobby.

What has been here said about the saving of the waste hyposulphite of soda from fixing prints, applies with equal force to that employed in the fixing of negatives, whether on glass plates or paper.

PATENTS COMPLETED.

AN IMPROVED INDICATOR AND LOCK FOR THE SHUTTERS OF PHOTOGRAPHIC DARK BACKS OR SLIDES.

No. 3325. FREDERICK HAZELDINE, Lant-street, Southwark.—*March 9, 1886.*

My invention relates to a combined indicator and lock for photographic dark slides or backs whereby the operator can ascertain at a glance whether the shutter has, or has not, been drawn out, and whereby the shutter is absolutely prevented from being accidentally drawn out a second time so as to give a double exposure to the same plate or film.

The invention consists essentially of a detent or latch capable of being set in such position as to permit of the shutter being drawn out once for the purpose of exposing the plate or film in the camera, and adapted to be automatically set in such other position on the pushing in of the shutter after exposing, that it will act as a stop to prevent the shutter being drawn out a second time.

One arrangement is as follows:—The detent is pivoted to the frame of the dark slide or back at one side of the shutter, and is adapted to engage with a notch in the edge of the latter. The detent is acted on by a spring, and it may be set in such position as to offer no obstruction to the drawing out of the shutter a first time, but on the pushing in of the shutter after such first withdrawal, it will be caused to assume a different position and to engage in the notch of the shutter, so as to prevent the withdrawal of the shutter a second time. The detent may be pivoted between the two limbs of a U-shaped spring, which alternately acts on the detent at opposite sides, the other limb for the time being acting as a stop, but the spring may be otherwise arranged so as to accomplish the same end. For instance, a single spring may be so arranged as to act on the detent in opposite directions from its two extreme positions.

According to another arrangement the spring detent or latch is placed at the end of the dark slide or back, so as to engage with the inner end of the shutter. In this case the detent is hooked and engages with a stud, or its equivalent, on the shutter. The detent may be set for the withdrawal of the shutter by being held back out of engagement with the said stud by a shoulder on the shutter. On the withdrawal of the latter the detent or latch falls into such position as to engage with the stud on the shutter being pushed in, so as to prevent the withdrawal of the shutter a second time.

The claims are:—1. The combination with a photographic dark slide or back, of an automatic locking device, constructed and operating substantially as herein described and shown in the drawings, so that when suitably set it will permit the withdrawal of the shutter of the dark back once, and will, by the act of pushing in the shutter after such withdrawal, automatically lock the shutter in the closed position substantially as specified. 2. The combination with a photographic dark back or slide of the automatic locking device and indicator substantially as herein described and illustrated in Figures 1 to 5 of the drawings, and consisting of a spring actuated detent or latch, and of a notch or shoulder for engagements therewith, the detent being arranged for operation at the side of the shutter as specified. 3. The combination with a photographic dark back or slide of a spring-actuated hooked detent, and of a fixed catch for engagement therewith, the detent being arranged for operation at the end of the shutter as specified.

A NEW OR IMPROVED ADJUSTABLE DIAPHRAGM FOR PHOTOGRAPHIC CAMERAS.

No. 3879. WILLIAM JAMES LANCASTER (trading as J. Lancaster & Son), Colmore-row, Birmingham.—March 19, 1886.

My invention relates to photographic lens diaphragms, employed in photographic operations, to determine and regulate the amount of light that shall be admitted into a camera; thus the time for exposure in photographic operations depends upon the light upon an object about to be taken, and the size of the aperture of the diaphragm used with the lens.

Usually a series of various-sized diaphragms are employed, or rather a series of diaphragms with various-sized holes. This is objectionable, inasmuch as there is no means of varying the difference between the size of one aperture and the size of one above or below it, so as to give a mean difference.

By my invention the diaphragm is made adjustable, so as to be able to control the size of the aperture, according to the varying requirements and will of the operator; thus the aperture in the diaphragm is expanded or enlarged in such a manner that an infinite variety of apertures can be readily obtained.

The diaphragm or series of plates which constitute the diaphragm, form a part of the mount of the lens, thereby avoiding any loose diaphragms or parts whatsoever; and further, the aperture necessary for certain conditions of light can be predetermined by an index finger, before the former of which the latter travels.

The adjustable diaphragm is constructed as follows:—

Within the inside, and crossing the lens tube, is a circular plate or disc with a hole in its middle, of the full size which the aperture in the diaphragm can acquire; the diaphragm is a compound or segmental one, made up of a series of thin plates overlapping each other, but so disposed or arranged with respect to each other that their radial curved inside ends or parts enclose a circular or nearly circular space or opening; so that on the concave or curved inside edges of the ends of these plates being moved or made to approach each other, a greater or less aperture or hole is thereby produced.

The parts constituting the diaphragm, and the manner in which the curved or crescent inside edges of the plates are made to approach and recede from each other, is as follows:—

Each plate of the series of plates consists of a plate concave at one end to the radius or about the radius of the larger-sized aperture which the plates will make when fully opened out or expanded. This curved part forms the inside end of the plate. The other or outside end is pivoted or hung eccentrically upon the inside of the disc, with a hole in its middle as before described. The said pivot forms a centre upon which the plate turns inwards or outwards, in approaching or receding from the centre of the lens tube; and situated below, and somewhat in a line with the said centre, is a stud or pin, upon the face on the side of the plate, which engages and works within one of a series of radial tangential slots cut within a plate or disc with a hole in its middle, which works or is moved in front of the series of plates by a protruding arm or finger working through a slot cut in the outside tube of the lens.

Each of the said plates constituting the diaphragm are pivoted, and have studs like the one described, and each of the said studs of the series work within the slots as described; and further, each of the plates overlap each other, so that the edges of the one extend over the edges of the other, so as to form as it were a solid plate, but with an aperture that is able to be increased or decreased in size at pleasure.

Upon the top, outside of the lens tube, and in front of or surrounding the slit through which the finger works, is an index or graduated scale before which the finger is moved, so that a person, by moving the finger in front of one or other of the numbers or figures upon the scale, can have the size of aperture required. Thus the top scale may be 4, 6, 8, 10, 12, onwards, and bottom or second line "speed" 1, 2, 3, 4, &c.

The moving of the index finger or arm through a quadrant of a circle for closing, or for obtaining a smaller aperture, the studs on the plate of the series of plates, which may be six, eight, or any other suitable number, are made to travel down the tangential slots or slits, and each plate is at the same time turned inwardly upon the pivots upon which they are hung, thereby causing the curved inside ends to collectively approach each other and make a contracted aperture. When a larger aperture is required the arm or finger is only required to be turned in the reverse direction, when the plates are collectively made to slide over each other, and recede from the middle or axis of the lens, by turning eccentrically upon the pivot upon which they are hung, and by the studs on their sides travelling up the slits on the disc or plate wherein they are formed being partially rotated.

A supplementary disc, with a hole in its middle, comes in front of the plate with the tangential or inclined slits, in order to preserve or protect the same from injury or otherwise.

The claims are as follows:—1. A photographic lens diaphragm, or a diaphragm for photographic purposes, with, or provided with, an adjustable aperture or opening which admits of a variable expansion and contraction, and which said diaphragm consists of a series of thin plates (or two or more plates) or the equivalents of plates, which respectively overlap or underlap each other, preferably at their inner radially-curved gapped parts; so that on the said plates or their equivalents being collectively moved to or away from a common centre a varying-sized circular, or nearly circular, or other shaped aperture or opening is thereby obtained. 2. An adjustable photographic lens diaphragm, consisting of a series of pivoted swinging plates which overlap or work one upon another in such a manner that their inner concave gapped parts are made to enclose and form an aperture more or less circular, and which said plates are operated, or opened out, or drawn together, for giving a greater or less opening, by a plate (turned by a ring or finger) provided with, or having cut therein, tangentially or other eccentrically arranged slots or gaps wherein pins or their equivalents carried by the said plates work, the parts being arranged, combined, and operated in the manner and for the purpose herein described and set forth. 3. A photographic lens diaphragm with an adjustable aperture composed of a series of overlapping radially-disposed plates with their inner ends concave or gapped, which on being radially drawn together or opened out produce varying-sized apertures, substantially as described. 4. Combining with a lens tube, an adjustable fixed diaphragm. Also providing combined lens tubes and adjustable diaphragms with graduated scales or equivalents thereof, for the purpose substantially as described and set forth.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

At the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, on Thursday, March 10, Mr. L. Medland presided.

Mr. A. L. HENDERSON asked of what "anti-calcaire," an advertised substance for removing lime from common water, was composed. Added to a solution of gelatine it made it thin during the night and left a precipitate at the bottom. The solution had a taste something like soda; there appeared to be lime in it, for some of the "anti-calcaire" would not dissolve.

Mr. W. H. HARRISON thought that it might be hydrate of lime, which was added by certain water companies to waters holding bicarbonate of lime in solution, the whole of the lime being then precipitated as carbonate. Oxalate of ammonia was capital stuff to precipitate lime from water. In both these cases a mere trace must be added to precipitate the lime in the water; there should be no excess.

Another speaker said that it might be "soda lime," which was much used in analytical chemistry for the purpose.

The question was asked, "What is the best method of drying collodion-bromide emulsion after it is washed?"

Mr. HENDERSON: The centrifugal separator.

Mr. J. B. B. WELLINGTON used methylated spirit.

Mr. A. MACKIE said that Mr. W. B. Bolton had published that methylated spirit for the purpose injured the emulsion in most cases.

The HON. SECRETARY had tried Mr. Bolton's formula as published in the ALMANAC, and it did not work in his hands.

Mr. ATKINSON dried the emulsion by the aid of a sand bath.

The CHAIRMAN dried it by squeezing it in a vice.

The HON. SECRETARY had dried it effectually with a lemon squeezer. Imperfect drying was the chief cause of failure of those who first began to work the process.

Another question was, "What is the best method of reducing over-dense collodion transparencies?"

Mr. WELLINGTON recommended the ferricyanide of potassium and thio-sulphate of soda method.

Mr. MACKIE asked if anyone had ever tried the ferric-oxalate method recommended by Mr. W. Willis.

Mr. A. HADDON said that the ferric-oxalate must be followed by hypo.

Another question was, "What is the best work on photographic chemistry?"

Mr. HENDERSON: Hardwich's, edited by Mr. J. Traill Taylor.

Mr. J. TRAILL TAYLOR exhibited some photographs taken in Paris by the electric light, as published in last week's JOURNAL, and sent to him by Professor Stebbing. No better photographs could be taken by daylight, and what had been done by the electric light ought to be possible by the magnesium light, which was much cheaper. A good way of getting rid of the smoke of magnesium was to burn the metal in a close vessel furnished with a long wire-lined tube of common calico, of large diameter, the further end of the tube being made to pass out of the window. Grant and Solomon's magnesium lamp would do to pass out the riband for burning.

Mr. HARRISON said that the price of magnesium bore relation to the price of sodium, so there would probably be another great fall in cost, for within the last month or two Mr. Castner had found out how to make sodium at 8½d. a-pound, instead of about 4s. a-pound as heretofore; the selling prices of the sodium would, of course, be higher. Furnaces had been erected for the manufacture.

Mr. TAYLOR stated that there were sufficient demand for it, magnesium, as made at present, could be sold at a shilling a-pound. Magnesium in powder had been burned with success at some of the *conversations* at one of the meetings of the British Association; the first night the light was offensively cold; the second night they added too much strontium to the powder, and the light was offensively pink.

Mr. HARRISON said that powdered magnesium was cheaper than the riband in first cost, and could be burnt for photographic purposes to more advantage than the other, and without danger of the light suddenly going out.

Mr. HENDERSON remarked that a Glasgow man had a good way of burning magnesium in oxygen.

Mr. G. D. Plomer exhibited Hart's hand apparatus for burning magnesium riband.

An exhibition of lantern pictures followed; Mr. Medland contributed zoological subjects and views of India and Yarmouth; Mr. C. H. Cook, views taken in Sussex; Mr. Wellington, general views, and views on the Banks of the Wye; Mr. Thomas Kerr, copies of conical engravings; and Mr. Harrison views taken in Switzerland.

Mr. J. G. Kitchener and Mr. Davenport Knight were elected members of the Association.

The meeting then broke up.

CAMERA CLUB.

On Thursday, March 10, Mr. Norman Macbeth, R.S.A., lectured upon artistic composition. Mr. Adeock occupied the chair.

Previous to the reading of the lecture, Mr. H. J. Gifford exhibited a Newman shutter which was made to fit into the diaphragm slot, was worked by com-

pressed air, and gave exposures from what was claimed as one one-hundredth of a second to any desired length of time.

Mr. Alfred Deed handed round some deeply interesting photographs of large size, showing some effects of the recent earthquake at Mentone.

Mr. MACBETH then proceeded to give his address, *On the Composition of the Pictorial*. The lecture was illustrated by diagrams and pictures shown by the optical lantern, and it treated chiefly of rules of guidance as to selecting the most effective boundaries for pictures and as to the arrangement of the principal objects so as to secure pleasing balance and effect. In regard to the proportions of pictures, Mr. Macbeth stated that the smaller of the two dimensions being fixed upon, the length should be obtained by taking the diagonal of the square formed upon this smaller dimension. This surface should be divided up into subdivisions of uneven numbers. Leading objects and those placed or composed to balance them must be on the intersections of these lines, if a pictorial representation is to be secured. After giving the substance of the lecture, which had already appeared more fully in the photographic papers, Mr. Macbeth went *seriatim* through a selection of pictures thrown on the screen, explaining how their boundaries had been fixed and objects placed according to these rules. The greatest stress was laid on the use of such rules of guidance in deciding the limits of a pictorial composition when trimming the photograph.

The CHAIRMAN, in calling for discussion, expressed his satisfaction at having acquired some new and useful knowledge from the lecture. He had come one hundred and four miles chiefly to hear Mr. Norman Macbeth. He knew that discrimination and courage were required in trimming photographic pictures to their most pictorial proportions, and said that much more attention should be devoted to this point by photographers. Many of Mr. Macbeth's remarks and those indications of figures which he had painted in where required upon the lantern pictures showed us a weak point in photography as compared with painting, namely, the difficulty in regard to placing figures or objects, such as cattle or ships, in just the place where there was a felt want. He had been greatly gratified at seeing some of Mr. H. P. Robinson's fine work upon the screen.

Mr. W. K. BURTON said he felt the art side of photography somewhat out of his domain. In regard to so-called instantaneous exposures, Mr. Macbeth had stated or inferred something which was not quite correct when, as he understood him, he suggested that much error could not be made in shutter exposures. There was just as great a difference in effect on the plate between one-tenth and one-twentieth of a second in rapid exposures with large apertures as between ten and twenty seconds in long timing.

Messrs. DAVISON and RODGERS expressed some scepticism as to the value and reasonableness of the system proposed by the lecturer.

Mr. WOLLASTON asked whether the old masters built up their compositions by recourse to a mathematical arrangement to find "*forte*" points.

Mr. H. H. O'FARRELL questioned whether the theory of *forte* points, like other art rules, was not capable of being over refined, and pointed out that in one picture exhibited by the lecturer and divided by him into seven divisions there was an object of interest in each division. He thought that rules of art could never be said to be firmly based unless capable of an explanation grounded on the physiology of vision. The eye, for instance, had only a very limited range of vision, and was constantly travelling over the object viewed. The *forte* points might possibly be explained as being situated on the extreme edges of the area of distinct vision, and thus forming a series of steps leading the eye across the picture. So, again, if a curve were more pleasing to the eye than a straight line, the reason probably was that the eye moved over a curve with less muscular effort than along a straight line. Whatever might be thought of these examples, it seemed clear that until some scientific basis was found all canons of art must be more or less unsatisfactory.

Mr. MACBETH, in reply to criticisms, stated that those pictures, thrown on the screen without the lines on which the composition was arranged being shown, had been felt as pleasing, but they had been treated in the same way as those exhibiting the subdivisions. In seeking to construct a composition pleasing in regard to balance and arrangement, he did not see what else besides such a system there was to rely upon. He would emphasise it particularly in regard to the fixing of the final boundaries of the picture in trimming. As to Mr. O'Farrell's remarks in regard to the picture showing seven figures in a line across the picture, each on a *forte* point, he would say that he did not suggest the plan as serving more than merely an indication in instantaneous work. It would assist in making the best possible arrangement of such a picture when fixing the boundaries.

A hearty vote of thanks was accorded the lecturer for having opened up a most interesting discussion and for having directed attention to the subject of artistic composition in photographic work.

On Thursday, March 24, the subject is *Alpha Paper*, to be opened by Mr. G. Davison.

BIRKENHEAD PHOTOGRAPHIC ASSOCIATION.

The ordinary meeting of the above was held on Thursday evening, March 10, at the Free Public Library.—Mr. J. A. Forrest (President) in the chair.

Messrs. James Fullerton and H. Wilkinson were elected members of the Association.

Messrs. W. Watson & Sons' new detective camera was exhibited during the evening, and excited interest on account of its novelty.

Some discussion was raised by Messrs. P. LANGE and H. N. ATKINS on the merits of the improvement in glass being introduced by Mr. Abbe, of Jena, under the auspices of the German government. It was prognosticated by them that 1887 would be a Jubilee year for photographers, so great would be the improvements in lenses as regards optical properties and price, the latter "a consummation most devoutly to be wished."

The chief attraction of the evening was a lantern exhibition illustrating *A Tour through Holland*, a number of splendid slides, nearly all from instantaneous negatives, being kindly lent for the occasion by Mr. Bernard Conlon, Mount Pleasant, Liverpool, which depicted the topography and social life of that flat country in a most vivid manner.

Mr. WILLEM S. LOGEMAN, "native here and to the manner born," "personally conducted" the tour, and before the close of the evening had considerably impressed his audience with the amount of historic and general information he was possessed of, for, as the VICE-PRESIDENT remarked, when proposing a vote of thanks (which was accorded with more than ordinary cordiality), he felt as if he had just returned from travelling in Holland, and that, too, with much pleasanter recollections than if he had recently crossed the North Sea and paid the customary tribute to Neptune, a tax his marine majesty most zealously enforces, as those who have travelled *à la Grimsby* or Harwich will painfully recollect. Amsterdam and Rotterdam of course afforded the largest number of views, but besides these places visits were paid to Dordrecht, Delft, Scheveningen, Leyden, Haarlem, Ackmar, Hoorn, Marken, La Haye, Utrecht, &c. Mr. A. W. Cornish manipulated the lantern.

The annual dinner of the Association was held on the 5th instant at the Grand Restaurant, Argyle-street, under the chairmanship of the President, supported by Mr. Paul Lange as Vice.

After the usual loyal toasts the Chairman said he rejoiced in the continued success of the Association—an Association which had his warmest affection and excited his deepest interest; an Association whose birthplace happened to be the very room they were then occupying, and where harmony and good feeling prevailed so generally; and an Association over which it gave him the greatest delight to preside. He concluded with a fraternal greeting to all followers of the "black art."

Messrs. Falton and Lange entertained the party with some charming German songs and choruses, while M. Gillon ably represented *La Belle France*. Mr. J. H. Day's fine rendering of a German song met with great approval and applause, as it deserved. Mr. B. J. Sayce, one of the pioneers of photography, and the photographic gold medallist of the Inventions Exhibition, a gentleman of whom the Association is justly proud, gave a charming Scotch song with bagpipe chorus while the "Anvil Chorus," from *Travatore*, with penknife and tumbler accompaniment, proved an attractive item.

Thoughts of Mrs. Candle sitting up at home acted as an all-powerful "reducer," the meeting breaking up at a respectably early hour, all thoroughly pleased with their evening's enjoyment.

DERBY PHOTOGRAPHIC SOCIETY.

THE members of the Derby Photographic Society held their usual monthly meeting at their rooms, 33, Victoria-street, on Tuesday, March 8, when Mr. RICHARD KEENE exhibited and described over one hundred lantern slides made and lent by Mr. J. B. B. Wellington, of London, which were greatly admired by the members present, of which there was a large number; and a unanimous vote of thanks was accorded to Mr. Wellington for lending the slides, to Mr. Keene for his description of them, and to Mr. Saxelby for the use of his lantern.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

THE usual fortnightly meeting was held in the Council Chamber of the Midland Institute on the 10th instant. There was a crowded attendance of members and friends, Vice-President W. J. Harrison, F.G.S., in the chair, and the minutes of the last meeting were read and confirmed.

Mr. J. Pumphrey was nominated for election.

The CHAIRMAN announced that the meeting would be made special for the purpose of exhibiting the lantern slides sent from America, the use of which was given by the courtesy of the Camera Club of London.

The slides, numbering about two hundred, were then shown on the screen, Messrs. Karlse and Place manipulating the lantern and slides. Many of the pictures were of great beauty and elicited much applause, the instantaneous views of moving steamboats, &c., being exceptionally meritorious.

On the completion of this series of views, Mr. CHARLES PUMPHREY moved a vote of thanks to the Camera Club for the loan of the slides, and mentioned the great use to amateurs of being able to see the productions of other societies, thus creating by criticism a sort of friendly rivalry to gain as far as possible the *par excellence* of photographic scenes and pictures.

Mr. A. ROBINSON seconded the motion, and it was passed unanimously.

The remainder of the evening was devoted to the exhibition of a number of slides made by the members themselves, and which forms the nucleus of the collection being got together by the Birmingham Society which it is intended to lend to other Societies in exchange for the loan of theirs for the purpose of exhibition at their different meetings.

At the conclusion the Chairman announced the subject for the 21th instant, namely, *The Humorous Side of Photography*, by Mr. J. W. Welford.

LEICESTER AND LEICESTERSHIRE PHOTOGRAPHIC SOCIETY.

A REGULAR meeting of the Society was held on the 9th instant in the Mayor's Parlour, Old Town Hall,—the President, Mr. George Bankart, in the chair.

There was a good attendance. Two members were balloted for, and unanimously elected.

The President then introduced Mr. PILSBURY, who gave his paper on *Composition in Photography*. Coming from such an eminent authority, the remarks were received with deep attention, and the various points touched on were at once recognised, and the lecture was such that every one present duly appreciated the hints and information given by no sparing hand. Mr. Pilsbury opened by saying that while he could not speak to photographers as a photographer, his knowledge of the science being quite nominal, yet he could speak to them as one who could advise as to the best means of obtaining truly artistic and pictorial effects. Each point introduced was illustrated with an example either by photograph, drawing, or sketch on the blackboard, which materially assisted the members in grasping the idea he wished to convey.

The principal feature to be avoided in landscape photography was the introduction or repetition of straight lines or geometric forms, which could frequently be avoided by changing the standpoint of the tripod, and the undulatory form of outline was to be sought rather than any other to enhance the pictorial value of the photograph. His remarks as to lighting a picture were such as to completely revolutionise the ideas of most of the members, and yet when brought home by illustrations were incontrovertible.

The attention of the members was maintained until a late hour without any symptoms of flagging interest, and at the close, on the motion of the President, a hearty vote of thanks was tendered to Mr. Pilsbury and carried with acclamation.

SHEFFIELD PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society was held on Friday, the 4th instant (postponed),—the President, Mr. T. S. Yeomans, in the chair.

The minutes having been confirmed, discussion was invited as to fixing the excursions of the coming season. Finally it was determined that there should be three whole-day excursions, namely, to Haddon Hall, York, and Dove Dale, on some Wednesday or Thursday, as might be arranged by the Council according to convenience.

The Competition subjects were then proposed, and from which six were then determined by vote as follows:—"Sunshine and Shadow," "Old Building within Ten Miles of Sheffield," "Country Life," "Animal Life," "Street Scene in Sheffield," and "Workshop Interior."

Mr. C. F. Coombe was elected a member.

The PRESIDENT announced his intention of offering a prize for competition.

In order to give the smaller plates a chance, it was proposed to give a prize for the best series of three views taken on half-plates and under during the season; the original plate to be printed to its full dimensions, and not to be cut down from a larger size.

After arranging a few remaining details as to the forthcoming *conversations*, the meeting broke up.

A *conversation* was held by the above Society on Wednesday evening in the Masonic Hall, and was well attended. A large number of views, chiefly the work of the members, and embracing the various prize and competition pictures of the past season, were exhibited on the walls of the Hall, and there were also shown specimens of appliances, &c., used in connection with the art of photography. The members' work was, in many instances, of high merit and fully equal to that of professionals.

Mr. E. H. Pearce lent H. P. Robinson's *Sunset and Dawn*.

Photographic materials and appliances were exhibited by Hebbert Brothers, who had on view one of J. R. Gotz's newest pattern cameras. Cubley & Preston also showed an assortment of cameras, tripods, and dark-room requisites, and Taylor Brothers one of their newest whole-plate cameras. Mr. J. Barber showed his newly patented dissolver for the limelight, also a nicely got-up "saturator" for the ethoxo light. Mr. G. W. Atkins lent, amongst other objects, a photo-micrographic apparatus attached to his camera for enlarging microscopic objects, also a microscope depicting the eye of a dragon-fly; in each facet of which a portrait or other object was seen, showing thereby that each facet contained its own lens.

Mr. J. W. Charlesworth exposed and developed some photo-micrographs with the aid of a portable dark room, lent by Mr. G. Bromley, his microscope being lighted by means of a small electric lamp.

Mr. Bromley had some fine stereoscopic prints, also a microscope showing micro-photographs.

During the evening a large number of views, taken by the members, and showing places of interest in Sheffield and neighbourhood and other places in England, were thrown upon a large screen by Mr. C. Yeomans, Hon. Treasurer, by means of his optical lanterns illuminated by incandescent electric light—a novelty to most of the audience. The lamps were worked by thirty-two cells of an improved mercurial battery of the single liquid class, and showed a good ten-feet disc, being but little inferior to the blow-through jet, against which, however, it was not expected to compete.

Some very fine examples of photo-micrography, by the Woodbury process, comprising foraminifera and other shells, blow-fly's tongue, &c., were also displayed: these being probably some of the finest results attained in this direction.

Mr. J. A. Rodgers presided at the pianoforte, and gave selections of operatic and other music at intervals.

BRADFORD AMATEUR PHOTOGRAPHIC SOCIETY.

THE second exhibition of this Society is now open in the Bradford Art Gallery and Museum. About two hundred pictures comprise the exhibition, the work of members of the Society. The subjects treated are as varied as are the resources open to the student of the photographic art, whose artistic instincts may lead him to plant his camera in the sylvan glades or mossy dells of his own country, or impel him to try his hand at Alpine scenery; and considering that this is only the second season of the Society, the exhibition is said to be one of a most creditable character. As an adjunct to the collection of paintings and objects of art now on view in the Art Gallery, the exhibition is an acceptable and appropriate contribution. The exhibition also takes the form of a competition, the coveted honour being the silver medal awarded in each class, a bronze medal being given as second prize. Prizes are awarded for the three best pictures in each class. The exhibits were judged by three professional artists, namely, Mr. W. Eskett, York; Mr. T. Illingworth, Halifax; and Mr. J. Gunston, Bradford: when the following awards were made:—Class I., "Best landscape on full plate and upwards:" first prize, H. Forsyth; the second prize was awarded to D. G. Law. Class II., "Best landscape half-plate and under full-plate:" first prize, M. B. Wallace; second prize, D. G. Law. Class IV., for "The best instantaneous photograph:" first prize, W. S. Smith. Class V., for "The best interior:" first prize, G. L. Salt; second prize, W. H. Scott. Class VI.

"Best architectural subject:" first prize, H. Forsyth. For the "Best portrait," and the "Best composition picture," "Highly commended" was attached to photographs by G. L. Salt and C. H. Smithson. Mr. J. E. Fawcett also exhibits, "not for competition," an interesting group of photographs, representing natural objects, photographed with the microscope. We understand that the exhibition will be open for a few weeks.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Committee of this Association met at 181, Aldersgate-street, on the 7th instant,—W. Bedford, Esq., in the chair.

The minutes of the previous meeting were read and confirmed.

Messrs. T. Bedding, Edwin Cocking, J. Crocker, J. Humphries, E. T. Hiscock, H. Keen, H. J. Klosz, E. G. Priddle, J. A. Rigby, F. A. De Saulles, O. A. Smith, A. Spiller, T. Watson, L. Wolff, and E. De Zuccato were elected members of the Association.

The correspondence having been dealt with, the meeting discussed at considerable length various methods, having in view the desirable object of extending the knowledge of and obtaining additional strength to the Association numerically and financially, feeling sure that all cognisant with the aims of the Association would appreciate and support the Committee in their efforts to help the unfortunate.

Having heard with regret of the accident to the Rev. A. Tooth, who had placed a vacancy in his Orphanage at the disposal of the Association, a vote of sympathy was passed.

CARDIFF AMATEUR PHOTOGRAPHIC SOCIETY.

THE March meeting of the above Society was held on the 11th instant,—Mr. S. W. Allen, the President, in the chair.

The arrangement for Mr. T. C. Hepworth's lecture was confirmed for the 23rd instant, and will take place at the Lesser Park Hall.

The Secretary was instructed to obtain an album, contributions for which will be solicited from the members, and when filled presented to the Cardiff Infirmary. If sufficient prints are received it is proposed to present albums to other institutions of the town. The Hon. Secretary would be pleased to receive contributions from friends at a distance.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE monthly meeting of the Association was held on March 3, in the Rooms, 207, Bath-street,—Mr. Lang, F.C.S., in the chair.

Minutes of last meeting were read and confirmed. Mr. Thomas Nisbet was unanimously elected a member.

A quantity of apparatus sent by Mr. A. L. Henderson, London, was shown, and caused great interest among the members. Among the things sent may be mentioned the following:—Calotype camera, emulsion distributor, spectacles for dark room, pictures with green fog showing optical result, pinhole camera with pictures taken by same, specimen of isochromatic photography produced by the intervention of yellow glass between the object without any staining of the plate, photograph taken by gaslight of the dinner of the London and Provincial Photographic Association, &c. After they had been viewed by the members, and a good deal of discussion and questions asked regarding them, the CHAIRMAN said the Association was greatly indebted to Mr. Henderson for these interesting exhibits, he therefore proposed that a vote of thanks be accorded Mr. Henderson, which was given.

Thereafter the CHAIRMAN called upon Mr. William Goodwin to say a few words about isochromatic photography.

Mr. GOODWIN said that this was a subject he had lately given some attention to, and Mr. Lang knowing that asked him to come to-night and give the Association the benefit of his knowledge thereon. Some fourteen years ago chlorophyl and turnerie had been recommended for the purpose of making plates more sensitive to certain rays of the spectrum, but very little had been done in this direction until a few years since, when some of the dyes procured from coal tar had been used with marked success for this purpose. Amongst these were the eosines and the erythrosines, about which so much had appeared in the journals lately. In his experiments he could not say he had made any discoveries; he had contented himself by trying the various formulae which had been published, and he had got the best results with that published by Mr. Wellington. With this formula, however, he found that instead of soaking the plates in the carbonate of silver and erythrosine at the same time, it was better to soak first in the carbonate of silver and afterwards in the erythrosine, using the two separately. Mr. Goodwin proceeded by the aid of the black board to show by means of curves the effect of various dyes when used in isochromatic photography, remarking among the dyes that those only that had a chemical action on the film of the prepared plate were of any use. At the close of his remarks Mr. Goodwin passed round a series of photographs of a bouquet of flowers taken on ordinary and isochromatic plates, which showed the great advantage of the latter in coloured subjects.

A question asked by a member at Mr. Goodwin was: Seeing the wonderful result got by Mr. Henderson simply by the use of a coloured screen, could the same results shown in the photographs of the flowers not be procured without going to the trouble of staining the film?

In answer, Mr. GOODWIN said that he had begun experimenting in isochromatic photography on a scale of colour he had made himself, and had got some most extraordinary results, the yellow and the red photographing almost white. He could not for some time understand this, until he had examined the colours he had used in making the scale, and found that they were so much made up of white to give them body that they were useless for the purpose. He thought that something of the same kind was the explanation of the photograph sent by Mr. Henderson, as the yellow glass when used with an ordinary plate on a flower had no perceptible effect.

After a good deal more conversation, Mr. BELL proposed a vote of thanks to Mr. Goodwin for the interesting manner in which he had dealt with the subject of isochromatic photography.

This vote was responded to, the members having fully appreciated Mr. Goodwin's kindness in giving the Association the benefit of his knowledge in this department.

The evening being by this time pretty far advanced, several matters of interest were carried forward till next meeting, and the members separated.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE fifth ordinary meeting of the session was held on Wednesday evening, March 2.—The President in the chair.

A communication from Mr. ANDREW PRINGLE, entitled *A Jaunt in Spain*, was read, in which the writer described his experiences, photographic and otherwise.

Mr. F. BRIGLMEN gave a demonstration of the exposure and development of the Eastman bromide paper, using the formula recommended by the makers. The exposures were successfully made by magnesium light.

Mr. R. BOW, C.E., said that in his experience a short development tended to greyiness of tone, while a long and restrained treatment yielded a reddish or chocolate colour.

Mr. W. FORGAN thought that the best results were to be obtained by commencing the development with a weak solution, which permitted of complete control and allowed a deliberate judgment of the progress of the image. He got good black, but not brown tones, with Eastman paper.

Dr. THOMPSON, when first experimenting with the Alpha paper, two years ago, had conceived that if the same means employed for toning gelatine emulsions on glass were employed for paper films like results should follow, and he had found that to a great extent it was so. He thought that an exposure exactly suited to the character and density of a negative was required in order to secure the fullest detail possible and to approach the appearance of the silver print.

Mr. J. MCKEAN had not seen bromide paper to be so suitable for small work, and the probability was that its chief use lay in the making of enlargements.

Mr. WILSON said he had developed a good deal of Eastman paper, and had satisfied himself that a simpler formula than that published was quite efficient. He made a saturated solution of iron and a similar one of oxalate, and to three parts of the former he added one of the latter, the mixture being of a wine colour. This he found to act well, and he got purple-black tones. He suggested that a portion of an evening might also be devoted to the making of lantern transparencies.

Mr. Forgan exhibited some early examples of *cartes-de-visite* taken by Disderi, who might be called the inventor of this style of portrait. They were in a remarkably good state of preservation.

The Secretary exhibited Mr. F. Houghton's "Acme" dark slide and changing box. The slide division itself contains all the plates or films intended to be used, and which may easily consist of twelve plates or twenty-four films, each one being contained in a thin metal carrier, which, after exposure, is pulled by means of a small rod with a flat hook into the attached changing box, and the operation repeated till all are exposed.

A silver print fixed entirely by liquor ammonia instead of hypo was laid upon the table by Mr. Bow, who promised to speak upon the subject at the next ordinary meeting.

A number of large photographs of the Grand Observatory now being erected at Nice were exhibited by Professor C. Piazz Smyth.

Correspondence.

Correspondents should never write on both sides of the paper.

EXHIBITING AND EXHIBITORS.

To the Editors.

GENTLEMEN,—I regret that my health would not allow me to be present when my paper on *Exhibiting and Exhibitors* was read at the Photographic Society of Great Britain. Perhaps you will allow me to comment on so much of the discussion as you report and needs reply.

Captain Abney refers to an incident in ancient history—my first introduction to him. It is so long ago now as to make us very old friends, and perhaps to dim the accuracy of the memory of both of us; but as it affords an illustration confirming what I mention in the paper of the awkwardness of too many cooks, perhaps I may be excused for giving my impression of an incident which has otherwise only a personal interest.

On one occasion when I was helping to hang the pictures, I had arranged the frames for one side of the room much to my satisfaction, and went away for an hour. On my return I found a stranger, who had not appeared before the work was half done, altering my arrangements. The stranger was Captain Abney, and I think I told him rather freely that he was interfering with the part of the work I had undertaken. From that moment commenced an unbroken friendship I have always highly valued, and which is one of the many pleasures I owe to photography.

It is rather awkward to publish a discussion on a paper before the paper is printed. In my case it gives Mr. Debenham an opportunity of ingeniously suggesting that I endeavoured to insult a foreign exhibitor.

Foreign exhibitors know better than Mr. Debenham does that I always welcome their exhibits; indeed, I should be very ungrateful if I did not, for they receive mine with great cordiality. In the present instance I speak, in the paper, of this foreign exhibitor's work in the very highest terms, deploring only that the mounts, which the photographer probably never saw, were so vulgar in taste as to greatly damage the pictures as well as the general effect of the exhibition.

Mr. Debenham objects to my saying that the mounts were vulgar in taste on the ground that it *was* a matter of taste. As my paper was chiefly on matters of taste, I think I may be allowed to agree with everybody of taste except Mr. Debenham, that the mounts were vulgar. I am sorry to be compelled to agree with most people in disagreeing on this subject with Mr. Debenham.—I am, yours, &c., H. P. ROBINSON.

Tunbridge Wells, March 12, 1887.

AN IMAGINED DANGER FROM AMMONIA.

To the Editors.

GENTLEMEN,—Early last summer I took up photography as an amusement, using Trafalgar and Hford dry plates, which require amongst other chemicals for their developing ammonia. In the latter end of August I was attacked with most violent ophthalmia, never having had it before (although I must admit my eyelids have often been weak, especially in the summer). I was at a loss to find the cause, and it was rather naturally suggested to have been brought on by photography, probably from the fumes arising from the ammonia during developing. As I only just escaped from losing my eyesight I am very chary about taking to the work again, bitterly as I regret having to give up such a fascinating study.

In the first place, however, I should like to know whether photography really had anything to do with it, and in the next, provided it had, is there no means of taking thorough precautions against the danger? Could I use another developer? or if that could not be done advantageously, would the wearing of protecting spectacles be sufficient guard for the eyes?

I should be very interested to know if this affection is ever met with among the profession, and what steps are taken in cases of attacks.—I am, yours, &c., E. Y. E.

Lower Sydenham, March 14, 1887.

[Although we have never heard of ammonia acting in the manner described, yet it is not impossible it may have been the cause of the ophthalmia in this case. If so, then our correspondent may take comfort in knowing that the carbonates of potash or soda will render him independent of ammonia.—EDS.]

RETOUCHING.

To the Editors.

GENTLEMEN,—In last week's JOURNAL your correspondent "Hydra" puts a question which, I must confess, is not an over-easy one to answer. He says, "I should like to ask Mr. Barrett what he considers a fair day's work. Doing the negatives well, and working, say, from nine a.m. to six p.m., with an hour off?" I will try to give a satisfactory answer.

There are some photographers (and good ones, too) who would not consider twenty-four hours a-day (Sundays included) to be at all too much during the busy months, and so obviate the necessity of working at all (at the photographer's expense) during the slack season. But thank Providence—I speak feelingly—these samples are few. For a good retoucher, one who is quick and works hard while he is at it, personally, I consider ten o'clock quite early enough to begin, and he should be able to get finished by about half-past five p.m. Retouching has always come rather easily to me, so I made up my mind on reading "Hydra's" letter not to give my individual opinion as an authoritative measurement of a day's work, but conferring with a few fellow-workers on the matter, have come to the conclusion that one dozen of mixed negatives—that is to say, about three or four large heads (ordinary cabinet vignettes) and the rest cabinet three-quarters and full-lengths—may be considered a fair day's work, this supposing the negatives of a fair average quality. It is possible to get cabinet heads that two hours would be necessary to make them presentable. I knew a first-rate retoucher (a Russian) who considered six cabinet vignettes a good day's work. But really so much depends upon the quality of the negatives that it is almost impossible to give more than a suggestion as to what may be considered a fair day's work in this branch.—I am, yours, &c., REDMOND BARRETT.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting of this Club, March 23, will be *Old or Outlets*.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The usual monthly technical meeting of this Society will take place on Tuesday next, March 22, at eight p.m., at the Gallery, 5A, Pall Mall East, when the subject of *Bromide Prints* will be brought forward for consideration.

Exchange Column.

* * No charge is made for inserting Exchanges of Apparatus in this column; but none will be inserted unless the article wanted is definitely stated. Those who specify their requirements as "anything useful" will therefore understand the reason of their non-appearance.

Will exchange telescope, marine glass, and box of fairy bells, for a Ross' $8\frac{1}{2} \times 6\frac{1}{2}$ portable symmetrical lens or wide-angle rectilinear, same size.—Address, J. H. GORMAN, Fore-street, Dulverton.

Gentleman's eighteen-carat gold keyless English lever, demi-hunter, three-ounce cases, by first-class maker; exchange for photographic goods.—Address, PHOTOGRAPHER, 4, John-street, Bradford.

Half-plate mahogany bellows camera, swing back, repeating back, and extra back for cabinets; also Marion's embossing press for cards. Exchange for camera lens, head-rests, good interior background, or useful accessories.—Address, BARTLETT, 49, Dudley-street, Bilston, Staffordshire.

Answers to Correspondents.

NOTICE.—Each Correspondent is required to enclose his name and address, although not necessarily for publication. Communications may, when thought desirable, appear under a NOM DE PLUME as hitherto, or, by preference, under three letters of the alphabet. Such signatures as "Constant Reader," "Subscriber," &c., should be avoided. Correspondents not conforming to this rule will therefore understand the reason for the omission of their communications.

A. M. F.—We would give preference to the "rapid," which will nearly cover the larger size.

G. G.—We have not tried No. 1 on your list, but we can speak well of No. 2 from personal knowledge.

C. A. H.—Such a studio as you speak of is preferred by many. There is certainly no objection to ground-glass.

R. A. CORNELL.—Coignet's gold medal gelatine is not suitable for making gelatine reliefs for the Woodbury process.

T. EDGE.—The work on platinotype is published by Messrs. Harrison & Sons, 59, Pall Mall, W. The price is two shillings.

AMOURETTE.—See reply in the last number. A solution of protosulphate of iron will precipitate any gold that may be in the solution.

O. P. H.—We gave our authority for the formula, but we have not tried it ourselves. If you cannot get on with it try bookbinders' paste; that will very likely answer your purpose.

S. WEISS.—1. We are not acquainted with either of the two productions mentioned, but have no doubt that both are reliable.—2. Diluted ammonium sulphide is the best reagent.

LENS.—Any lens bearing the name you mention is certain to be good; but it is assumed to be genuine, and not a forgery. A "rapid" lens of sixteen inches focus or rather more will serve the purpose.

S. A. WALLIS.—We do not imagine that you will gain any advantage by employing orthochromatic plates in photographing a tubby cat. If puss were a tortoiseshell some advantage might possibly accrue.

INQUIRER (Hampstead).—The print enclosed is taken from an etched plate—probably produced by a modification of Fox Talbot's original process. Such plates are now being produced commercially under various names.

A. B. Z.—Most if not all of the scientific works published on the Continent may be obtained through Messrs. Trübner & Co. Other foreign booksellers will also procure them if they are furnished with the titles and the names and addresses of the publishers.

G. Y. G. inquires where the English translation of the work by Captain Pizzighelli and Baron A. Huld on the platinotype, alluded to in No. 1398 by Mr. W. H. Harrison, can be got or by whom published.—The English edition of the work in question is published by Messrs. Harrison & Sons, 59, Pall Mall.

GREENHORNE.—In the reply to your previous query there was a printer's error. If in place of *several* you will read *several* the answer will be plain enough. If it is not, and you will send us the lenses, we will help you further. Classes such as you desire are held at the Polytechnic Institution under the direction of Mr. Howard Farmer.

SCOTTS.—1. If light gains access to the lens otherwise than through the aperture in the shutter it will of course affect the plate.—2. There is nothing against the shutter whatever if it works well.—3. Whether or not the developer mentioned is the best that can be used for under-exposed plates depends very much upon the make of the plate.

H. J. GORIN informs us, in reply to Mr. Barrett, that Mr. G. Croughton, now in America, was never employed as a retoucher, or in any other capacity, by the late T. R. Williams; but he says "the managing partner, W. Mayland, engaged him after Mr. Williams was practically out of the business, and this to my personal knowledge happened a considerable time after retouching came into general use."

JUBILEE asks: "Can you assist me in a solution to the following little difficulty? I am using a double albumenised paper with a very high surface, but, do what I will, I cannot get the silver from the washings to precipitate. Whether I use a preliminary wash of alkali or plain water the result is the same, and if you can suggest a way out of the difficulty I shall be very pleased, as the time has hardly arrived when I can afford to throw silver down the sink. The paper is a ready-sensitised one."—If hydrochloric acid be employed in place of salt the precipitate will usually subside very quickly. The best plan is to add the acid and then stir the liquid vigorously for a few minutes.

B. P. writes: "Will you kindly inform me, through the medium of your paper, as to what materials I should use, and mode of applying them to linen, to form a plain distemper background?"—Distemper is made by mixing dry colour of the tint desired with water and common size, such as that sold by the oilmen. It is applied with a large brush, usually a white-wash brush. Only sufficient size should be used to prevent the colour from rubbing off when dry. The exact quantity can easily be ascertained by one or two trials.

STOREY says: "I have prepared a sensitising bath (silver) according to the formula recommended by Mr. V. Blanchard, in April, 1879. The paper works very well, but I find that the bath is turning quite brown. Can you advise me what to do with it? and do these baths usually turn yellow?"—Silver baths employed for sensitising albumenised paper usually becomes discoloured after a time. They can be decolourised by shaking them up with a little kaolin, when they will become as new. The works mentioned are not supplied by us. They may be procured through any of the dealers in photographic materials.

SAIPO says: "I have been trying to make some chloride of gold by Mr. Forrest's formula. I dissolved a nine-carat gold pin, about forty grains, and the result is a light green liquid. How can I get the colour out of it? or is it detrimental in toning?"—Mr. Forrest recommends the use of the current coin, which is twenty-two-carat fine, consequently the small quantity of alloy—two carats—does no harm. But our correspondent has used a metal containing thirteen parts of alloy—probably copper and zinc. Possibly this amount of base metal will do no harm, but that can be ascertained by toning some prints with it. As the amount of fine gold in the pin was but fifteen grains to begin with, it will not pay to devote the necessary time and trouble to the purification of the solution.

W. B. CASSINGHAM writes: "Will you please to inform me, in your 'Answers to Correspondents' column, if there is anything injurious in plain water for washing prints (albumenised) before toning, or would there be any advantage in using softened water (Maignen's anti-calcaire powder) as advertised? I use grooved troughs for my plates; they hold about four pints of solution each. I seldom have more than a dozen plates to do at a time. Is it necessary to throw the solutions away after using once only? Can they be kept for a week or two until the next batch of plates are ready, or is it best to make up fresh each time?"—It is not a good plan to use old fixing solutions. Hypo-sulphite of soda and alum are cheap enough, so it is better to use them fresh or not more than two or three days old. The stains on many negatives are caused by the use of old and sulphurised fixing solutions.

W. H. NEWTON writes: "I should esteem it a favour if you will inform me, in this week's JOURNAL, the cause of the spots on the enclosed prints. They are first to be seen after fixing; could they therefore be due to improper immersion on first being put in the hypo bath? In some cases the prints were dark and were left after fixing for the ordinary length of time in a very weak solution of hypo all night, to reduce them. Those marked on the backs with x were thus treated. Would small particles of verdigris from corroded taps be likely to cause them?"—The spots are due to sulphurisation, in all probability through air-bubbles adhering to the prints when they are first put into the fixing bath. We do not think they arise from particles coming from the tap. It is certainly a very bad plan to leave prints soaking in a dilution of hypo for a long time. The sooner our correspondent abandons this system the better.

FLORENT RUGREA says: "Would you kindly inform me, through your column devoted to 'Answers to Correspondents,' 1. Whether a magic lantern with five-inch condensers would be sufficiently large to enlarge from 5×4 negatives?—2. Are any of the enlarging papers at present in the market capable of receiving the tone and appearance of an ordinary silver paper?—3. Is there any method of removing from negatives without injuring the film the plain collodion used as a substitute for varnish?—4. Why am I often troubled with my varnish drying with a matt ground-glass surface? This obstructs the passage of the light and has forced me to discontinue using varnish."—In reply: 1. No. To enlarge from a 5×4 negative, if the whole is to be evenly illuminated, a condenser of not less than six and a half inches will be required.—2. Gelatino-bromide paper yields a colder tone than ordinary albumenised paper.—3. The collodion may be dissolved off without injury to the negative by immersing the plate in a mixture of equal parts of ether and alcohol.—4. Probably the varnish has been applied before the film was thoroughly dry, or may be the plate was not made sufficiently warm before its application. Either would account for the matt surface.

The catalogue of the Nottingham Photographic Exhibition is before us. It contains a large and varied collection, embracing a good deal of what was shown at the last London Exhibition.

An old member of the Photographic Society informs us, *apropos* of what we wrote last week concerning microscopical writing, that in the Jurors' Report of the International Exhibition of 1862 is a statement which on inferior authority would scarcely be credited, namely that the name and address of Mr. Matthew Marshall, Bank of England, has been written in the two-million-five-hundred-thousandth of an inch. If so then the whole Bible and Testament might be placed twenty-two times on the surface of a square inch.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1403. VOL. XXXIV.—MARCH 25, 1887.

SODA AND POTASH DEVELOPERS.

THERE can be little doubt regarding the growing popularity, especially among amateurs, of the addition of the carbonates of the fixed alkalies in preference to caustic ammonia to the pyrogallic developer, and in the course of the many conversations we have had with both amateurs and professionals, we have found that the constant nature of the former bodies, quite as much as the effects produced by their aid, has led to the abandonment of ammonia by so many workers—experienced hands as well as tyros. That the use of ammonia leads to grave uncertainty of practice has been irrefragably demonstrated. From the moment when, of very doubtful approach to the typical .880 specific gravity, it is purchased from the retailer, down to the time of being placed in the dish of developer, it is liable to continual fluctuations of strength, and consequent apparent irregularity of action, while the carbonates of soda or potash once purchased and kept with ordinary care are always supposed to be reliable.

Our present purpose is to show that there is in everyday practice the possibility of considerable error and irregularity in the use of these "constant" salts, a possibility brought about not by a single cause alone, and that the amount of error could be such as might easily exceed the extremest vagaries of ammonia.

At the outset, when we consider that these salts are, practically, only coming, and not come, into use, there is every opportunity for uncertainty from the actual names alone of these substances. Let us take, first, carbonate of soda. In America, which may be fairly termed the home of the soda and potash developers, the soda employed is recommended under the name of sal. soda. That is very good as far as it goes, for we are all told that it means "carbonate of soda"—nothing could be simpler. Let us look into the matter a little and investigate this simplicity. A photographer has heard from friends, and has seen in his journal, that carbonate of soda makes a splendid developer instead of ammonia, and upon the first opportunity he, determining to give it a good trial, sends his "boy" to the nearest chemist or, possibly, to the stores, or even to a grocer, for "an ounce of carbonate of soda." We undertake to say that in nineteen cases out of twenty he will be served with a white amorphous powder without a question being asked. He dissolves it in water and makes up a developer according to the formula he has had given him, or will find in his ALMANAC. The result will be very different indeed from what he would obtain if he procured the crystals of carbonate of soda. The real truth is that the carbonate of soda in crystals is the material intended to be used by the compounder of the formula; but the familiar white powder is so universally known under the name of "carbonate of soda," nice technical distinctions being ignored

by the general public, that unless it is actually understood by the experimenter that this confusion exists, the non-chemical reader would as an actual matter of course use the wrong material. Some would-be chemists glibly speak of sodium carbonate, and others again of sesquicarbonate or of bicarbonate, the truth being that the former term is too general and the latter older-fashioned and incorrect modes of speaking of what we may term this domestic chemical. There are three sodium carbonates, and to any one of the three is the term carbonate justly applicable.

The salt intended to be used is simply a pure sample of the familiar washing soda (of which more anon). It should be purchased at the chemists—preferably in the form of crystals—and asked for under the name of pure carbonate of soda in crystals. It is called by the technical chemists "neutral," or "disodic carbonate," and is found in commerce in the form of clear crystals. It also is to be obtained from the druggist as a dry white powder, the name under which they so know it being "exsiccated carbonate of soda," here again being a fruitful source of uncertainty. Our own opinion is that this latter is the name which should appear in formulæ. There would be little or no chance of confusion, and the product would be, if pure, always uniform, a quality not to be lightly disregarded when we point out that the crystals recognised by the Pharmacopœia contain sixty-three per cent. of water of crystallisation, that is to say, ten molecules; while it is quite possible to cause the salt to crystallise also with fifteen, nine, seven, and indeed with only a single molecule. We thus see that, both popularly and chemically, carbonate of soda, even if we limit the term to include the neutral carbonate only, is liable to extreme fluctuations of strength, and that a soda developer may not have a fair trial unless these conditions are understood.

Many photographers (if we remember aright, this was the case with the first publication of the formulæ) employ simple washing soda. We do not say it will not answer, but we do say that, if employed, extreme irregularity may be expected, for these crystals are very crude and impure, and may contain sulphates and chlorides in large quantity. These may possibly be non-injurious; but, if present in some and not in other samples, unequal results must be anticipated, both on the grounds of varying strength through the impurities and the possible restraining or other action they may possess.

It will now be fully evident to our readers, that if confusion is to be avoided and regularity be secured, some different and definite understanding must exist, or some other designation be employed. Our own recommendation would be that the "exsiccated carbonate of soda" of the Pharma-

copœia should be the substance selected; it is, perhaps, the most likely body to be procured at the chemists, and might be depended upon for evenness of composition and purity.

Turning now to the fellow carbonate, the carbonate of potash, we may admit that this chemical being so much less in demand has not a confusing popular name, and that if carbonate of potash were asked for at the chemists and druggists there would be little probability of confusion of terms as with soda. But we must point out that the one particular salt intended has no more right to the sole use of the term than has the soda compound, for there are two carbonates of potash or potassic carbonates (the latter being no more exact an appellation than sodic carbonate). The carbonate to be used is the normal or dipotassic carbonate, and is sometimes called subcarbonate of potash, also salts of tartar, and, more rarely, salts of wormwood. It is far less used in medicine than the acid potassium carbonate, or hydrogen and potassium carbonate, which is prescribed by the physician, and sold by the chemist as "bicarbonate" of potash.

But we must point out that this carbonate of potash is by no means an article of unvarying purity, so that, though in a less degree, our remarks upon soda crystals will apply to it. From all points of view, the carbonate of potash seems likely to become a greater favourite than that of soda.

We need not dwell further upon the topic; we trust we have shown, not only the possibility of confusion and irregularity, but also the need for a recognised exact nomenclature in formulæ for soda or potash developers.

COLOUR SENSITISING OR COLOURED SCREENS?

FURTHER experiments were made in which, instead of employing the coloured screen, the chart was illuminated by means of light passed through media of various shades of orange or yellow. The first of these trials, even when orthochromatic plates were employed, were so utterly devoid of any special colour effects that we were for some time at a loss to account for the result; we succeeded, however, at last in developing a theory, in explaining which we may be excused for going somewhat minutely into the details of our arrangements.

The colour chart in all our experiments was affixed to a screen placed at right angles with and close to a window, in a large apartment lit by other windows, the nearest of which is some fifteen feet away and so situated that no direct light from it could fall upon the chart. The walls, however, of the room being practically white, reflect a considerable amount of light on to the object over and above that which falls directly upon it from the window in close proximity. In the experiments with coloured media, this window was covered over with coloured tissues of various shades, from the so-called golden fabric to deep orange or even red paper. With the first-named material the colour was so light that to the eye little, if any, modification of the chart was apparent, and scarcely any variation of exposure was needful. But with the darker tints of orange and red the visual character of the chart was entirely changed; the yellows were entirely lost, and at a short distance not even the outline served to pick them out from the white ground. The various shades of orange appeared many degrees lighter—as yellows, in fact—and bright vermilion alone seemed to retain its original character amongst that class of tints. The blues, especially the brighter ones, much to our surprise, retained almost their pristine appearance, but the greens were changed slightly in the direction of blue.

With these *visible* changes of colour it seemed to us that there was a very strong hope, even with ordinary plates, of securing a marked modification in the rendering of at least the yellows. Our surprise may therefore be imagined when we found that when using the colour-sensitive plates the results given were precisely those obtained without the screen and with white light. The only effect of the coloured media was to necessitate a longer exposure; but, however much the exposure might be varied, there was no difference in the colour rendering. It is scarcely needful to say that with ordinary plates the case was precisely similar, except that the exposure was still further prolonged, though proportionately to that required by the orthochromatic plates not so much as we should have anticipated.

After repeated attempts to alter the results, all of which proved unsuccessful, we were naturally led to ponder the matter. Orthochromatic results, we were aware, are alleged to have been obtained not only in this manner but even with reflected coloured light. Why then, in our trials, were the results entirely negative? After some consideration it occurred to us that possibly the reflected white light falling upon the colour chart from the walls of the apartment might have some action in vitiating the orthochromatic influence of the coloured media. We therefore constructed a rough framework, by means of which the colour chart was entirely enclosed within screens of the same coloured material. The visual effect upon the different shades and tints of colour varied in no respect from that already described when the preponderance of illumination fell in one direction only from the coloured window, but the photographic effect upon the sensitive films was widely altered.

With ordinary plates there was still not the faintest sign of orthochromatic effect, but the exposure necessary when employing the same medium was very greatly increased as compared with that requisite under the former conditions. With the orthochromatic plates, however, while the exposure was but comparatively slightly lengthened, the resulting image possessed all the characteristics of those obtained when using the coloured screen in front of, or behind, the lens, thus demonstrating unmistakably the correctness of our suspicion with regard to the action of the reflected white light.

But the importance of the observation is in connection with its bearing upon the theory of the use of the coloured screen, and enables us, we think, to explain why, without colour-sensitised films, the screen proves practically useless, at any rate with a chart composed of artificial colours.

As was suggested by Mr. A. L. Henderson some little time ago, the proper way to test the orthochromatic value of films is to photograph the spectrum. So far as the orthochromatic *principle* is concerned this is undoubtedly true, but it would be far from an accurate guide to the practical application of orthochromatic plates to the reproduction of pictures. In the spectrum we have to deal with pure colours; pure, that is, not only in the sense that they are simple and not compound colours made from a mixture of other tints, but pure, also, inasmuch as they are not diluted or modified by an admixture of white light. Thus the blue of the spectrum is blue and not blue with an addition of white, and consequently it behaves as blue. In using a yellow screen for the purpose of photographing the spectrum, we are really photographing the absorption spectrum of that particular screen, and if it should cut off the blue rays entirely then even on an ordinary plate the blue will, being entirely absent, be rendered as black, while the particular rays which are freely passed by the screen, yellow for instance, will

have their active power proportionally exalted, and so be rendered with a nearer approach to white.

But the case is entirely different when a colour chart or a picture is photographed. We have then not only to deal with the colour, *qua* colour, but also with a more important item—the reflected white light. It has been stated, and no doubt correctly, that in photographing natural objects a far greater proportion of the photographic action is performed by the white reflected light than by the coloured objects themselves. In the case of copying coloured pictures, the case might be considered to be different, and no doubt would be if the pigments employed were pure spectrum colours, for setting aside the light inevitably reflected equally from the surface of the picture, we should have to deal more directly with the colours themselves than with reflections caused mainly by the forms of natural objects.

That reflected white light is the more important factor in photographic action, even with pure colours, is open to easy demonstration. If the sun be allowed to fall upon a prism and the spectrum intercepted upon a sheet of white paper be photographed either with or without a yellow screen, we get no more orthochromatic effect upon an ordinary plate than would be obtained from an artificial colour chart; though, if the same spectrum be allowed to fall *directly* upon the film itself we have, by the intervention of a coloured screen and without colour sensitising, all the effect that can be obtained with both.

If we accept the fact then that the greater part of photographic action is due to reflected light irrespective of colour, it is not difficult to understand why with ordinary plates the colour screen should, in the majority of instances, prove quite ineffectual; nor is it indeed difficult to see how, under some circumstances, the reverse may be the case. The effect of white light is so much more powerful than that proceeding from the mere colour, that the latter is practically masked, as shown in the first series of experiments recorded above. Here, though under the action of the coloured rays, a modification of the chart visible to the eye occurred, still the visually more feeble reflected white light quite overpowered it; when, however, the object was illuminated by coloured light only, the respective action of the blues and yellows may be considered as self-dependent, and the former being relatively more actinic than the latter was able to hold its own in spite of the unfavourable conditions of lighting.

It was remarked recently by Mr. W. E. Debenham, that a film rendered more sensitive to yellow would be at the same time rendered more sensitive generally, but especially to white light. This is quite our own view; but taking the converse, a film rendered less sensitive to blue rays by the interposition of a yellow screen will be rendered proportionately less sensitive to yellow as well. Therefore, in using a coloured screen, if any orthochromatic effect is to be gained, it can only be by chemically increasing the sensitiveness of the film to yellow rays in order that the retarding action of the screen may be counteracted.

We had a most favourable opportunity, a few weeks ago, of testing the orthochromatic method ascribed to M. D'Haow. The time was within half an hour of sunset in the latter part of February, and the sun lay low on the horizon undimmed by any cloud and of a deep red colour, surely conforming perfectly to the requirements of M. D'Haow's method, namely, comparative absence of blue or actinic rays. Three exposures were made of 30, 60, and 120 seconds, five seconds being the normal exposure required for an ordinary plate at midday. The result

was, in each case, but especially in the two shorter exposures, that the yellows and oranges suffered rather than otherwise in the rendering.

It is seldom that photographers, at least those dwelling in the neighbourhood of the Metropolis, have had within a few days of the vernal equinox such an opportunity of photographing snow scenes as they have this year. The heavy fall of last week furnished some excellent subjects for the camera, but, unfortunately, many of the results obtained which have come under our notice have been marred, and in some cases completely ruined as pictures, through over exposure. In some of the photographs in the brighter parts, which should have been represented by sparkling lights, there was decided indications of a reversed action. It should be borne in mind that, at the present time, the light, although the sun may not be visible, is of a much more actinic character than it was a few weeks back. The heat of the sun, coupled with a cold atmosphere, has produced some curious effects on the snow. In some places on one side of the road, where it has been sheltered from the direct rays of the sun, may be seen a thick coating of snow while the other is perfectly free. The same effects are seen where the snow has been shaded by trees. Photographs taken under these conditions are curious and interesting, though they may not be considered artistic.

Apropos of snow pictures, how should the snow be portrayed? In a painting it is always represented as being much whiter than the sky. In a photograph it is almost invariably rendered darker. Which is right? Visually, the snow usually looks much whiter than the sky, however bright that may appear.

On several occasions, in our back volumes, we have directed attention to the subject of ceramic photography, and pointed out the pecuniary advantage that would probably accrue to those who would make a feature of it in their ordinary business. We are not here alluding to small work on enamelled copper, but to larger sizes on porcelain. But so far as we are aware very little has been done in this direction by the profession. However, the matter now appears to have been taken up commercially, not by photographers, but by the dealers in earthenware and china goods. In a china shop at the West End, the other day, we saw some specimens of portraits burnt in on porcelain plaques, together with the announcement that enlarged copies from any photographers were supplied. The examples shown were exceedingly good, so far as the ceramic part of the process was concerned—the tones were deep and rich, and the colour pleasing; but the photographic portion of it was by no means satisfactory. The portraits had been enlarged, probably three or four diameters, from paper prints, and showed the grain to a painful extent. Even from paper prints, had they been judiciously lighted in the copying and skillfully retouched, much better results might have been obtained. Had the original negatives been employed, which would have been the case had the photographer executed the work, the results would be widely different. Successful ceramic photography is as much dependent upon the photographers' work as upon the potters.

Those who are in search of subjects for instantaneous photography should pay a visit to the different metropolitan markets during their business hours. Those who have only visited the London markets during the daytime have no conception of the animated and picturesque scenes to be witnessed in the early morning. Covent Garden, Farringdon, or Billingsgate Markets, present a widely different appearance at midday to what they do at five or six o'clock in the morning. A series of instantaneous photographs of such subjects would illustrate phases of London which would be exceedingly novel to a vast majority of the public. Of course, to secure these pictures, early rising, and a good light, are essential. The period is now fast approaching when the light will be sufficiently good to enable instantaneous effects to be obtained at a very early hour. In spring and early summer the atmosphere is usually clearer in London during the morning than it is later on in the day.

Now that the actinic quality of the light is so rapidly improving, those who employ natural instead of artificial light to develop by will do well to examine their dark room windows. The light coming through a window may be so non-actinic that it will not affect the most sensitive plate during the winter months and those of early spring, but not so as the summer advances. Here is a case in point. Foggy plates were frequently met with of late in a certain establishment, which, for some time, could not be accounted for, till at last the dark room window was suspected. This, upon testing, was found to be the cause. The window had been prepared, over two years ago, by covering a square of pale yellow glass with several layers of thin orange and red paper which then answered admirably. When the paper was removed the other day it was found that the action of light during the two summers had caused the sheets next the glass to fade considerably. The first one had most of its yellow discharged, and the second was but little better. Before a batch of plates are condemned for fog at this season of the year, it will be well, if daylight be used, to examine the dark room windows. We have, before now, heard of instances where yellow glass has changed colour through the continued action of the sun's rays.

TREES when they are devoid of foliage are rarely objects of interest, pictorially, to the photographer. But not so to the arborist. From a series of good photographs of trees, taken without their leaves, the student in arboriculture may acquire more knowledge than by almost any amount of reading. When trees are covered with foliage the fantastic forms of the branches of some, and the peculiarity of the bark of others, cannot, of course, be seen to advantage. This, therefore, is an excellent time to secure the photographs. The light is now good, and it will be a month or more before the trees put on their summer garments. In the Royal Gardens at Kew are to be found almost all kinds of trees, and every facility for photographing them will be given by the Comptroller. Application for tickets should be made in writing, and addressed to him at the Gardens.

DR. ROYSTON PIGOTT bears remarkable testimony as to the photographic power of microscopical objectives made with the new optical glass. He describes certain ruled gratings, made by Nobert, of such extreme closeness of ruling that the latter despaired of ever being able to see them in the microscope, and the exact number of certain of which rulings he kept secret. Dr. Royston Pigott says that Colonel Woodward sent him beautiful photographs of these bands, but the counting of the lines was precarious and bad, owing to diffraction lines being so plentiful. In old photographs of diatoms the same defect greatly marred the beauty of the pictures. But lately Dr. Van Heurck has sent him photographs taken with several new lenses, and those produced by combinations of the new glasses were so finely executed that the counting of the lines can be at last accurately performed. In these photographs, even when examined with a one-inch glass, "traces of diffraction are scarcely visible, and in many regions (speaking now of photographs of *Amphipleura pellucida*) altogether absent."

It is well known that the rough-and-ready hydrometer method of ascertaining the strength of silver baths is rejected by some of the more scientific manufacturers of ready sensitised paper for the more accurate plan of precipitation. We believe, however, that the Mohr system of using chromate of potash as an indicator to give, by a permanent change of colour in the precipitate, the point when complete decomposition has taken place is less generally adopted, though it is employed by some. It is, perhaps, as well that its employment should fall into desuetude, for, according to Mr. R. F. Carpenter (writing in the *Journal of the Society of Chemical Industry*), freshly precipitated chromate of silver is dissolved in solutions of alkaline nitrates. The writer considers there is here a complete explanation of the fact pointed out by a previous writer that the precipitation of the red chromate often takes place too late when nitrates, especially those of the alkalis and alkaline earths, are present. As it is evident that in well used silver baths there must always be present a large proportion of these nitrates, the photographic bearing of the observation is obvious.

PERMANENCE OF ARGENTIC BROMIDE PRINTS.

THE question of permanence of prints is still before the public, though it has turned into another channel from that which it originally took, and it now seems to be the turn of platinotype to be attacked vigorously with the essence of rotten eggs.

Last October I had an article on this subject, of which this is a continuation. We then started some experiments, which we have brought to a conclusion, only, as usual, to suggest something else. The preparation of the prints which we experimented with will be found in the issue of 1st October, 1886, and I do not think it will be necessary to recapitulate here.

In an article of 8th October, Mr. Pringle took exception to the fixing of the prints. In regard to this we had taken the precaution of placing about twenty-eight square inches of unexposed paper in the fixing bath, passing them through all the subsequent operations to the finishing of the prints; this we treated in the same way we had before treated the gelatine films scraped off glass, and got just the faintest trace of silver. I hope this will satisfy Mr. Pringle that the prints *were fixed*.

The prints were then cut up into three parts, one of which was put away, another into a test-tube having a solution of the gas to which it was to be subjected at the foot, and placed in a window having a west exposure, and getting the full benefit of the afternoon sun (when there was any), and the third was placed in a tube in the same way, and placed in a drawer so as to keep it in the dark.

No. I. was subjected to chlorine water, and, as we supposed, entirely disappeared in about twelve hours, having been converted into chloride of silver, which was proved by the image returning again by exposure to light to a certain extent.

No. II. was subjected to nitrous fumes, produced by acting on copper with nitric acid, and went entirely in about two hours.

No. III. was subjected to sulphuretted hydrogen, and on the third day was observed to have got a very slight tinge of yellow in the whites, which was more marked in the one exposed to light. It also seemed to be very slightly bleached. All the prints were under treatment for twelve weeks, except Nos. I. and II., which were destroyed, as above stated, at the end of that time. No. III., that part in the light, was very slightly yellow, in the whites was faded slightly, and of a very much richer colour. That part in the dark was also yellowed and slightly faded, but of not nearly so rich a colour as the part in the light.

No. IV. was subjected to ammonia, and on the second day was observed to have become slightly yellow, and also bleached, that part in the light being only slightly bleached, and the part in the dark markedly so. When they were taken out after the twelve weeks they were both much damaged; the gelatine seemed to have been slightly decomposed, and the whole thing was very tender. I may add that the films Nos. III. and IV., both in the window and the drawer, periodically got knocked over, and therefore the print was kept not only in a continuously saturated atmosphere, but also in a continually soaking condition. The result was that there was a certain amount of difficulty in getting them out of the test-tubes, and they most decidedly look like it.

I may mention that both the sulphurated hydrogen and the ammonia had been freshly prepared with every precaution, and the distilled water used in analysis, and which may be taken to contain little or no impurities, such as iron, &c.

No. V. was placed in sulphurous acid, and as there was none of known quality in the laboratory some was made, and the parts of the print sealed up in tubes filled with the gas as it came from the last wash bottle, and therefore saturated with moisture. There seems to be no change in this print after the twelve weeks; if changed at all it is, I think, very slightly bleached.

No. VI. was acted on by coal gas, and it was placed in a tube which was made a junction between two indiarubber tubes, which led the gas to a Bunsen which was in constant use in the laboratory, and therefore had a constant stream of gas passing over it, and which, at the end of about the four months, was unchanged.

These are the facts, and readers may draw their own conclusions from them. To me they appear very favourable to argentic bromide paper. In all instances it behaved in the way I should have expected it, except in its behaviour under ammonia.

The accepted theory of the developed image is that it is metallic

silver. In No. I. this is borne out by the silver when acted on by free chlorine, which even platinum cannot stand, was converted into the chloride, which is white, and which darkens by exposure to light.

Case No. II., nitrous fumes also converted the silver into the colourless nitrate; No. III., V., and VI., sulphide of silver being black, or dark brown, I was not surprised at the print taking a warmer tone.

The only case I am unable to explain is No. IV., where the print was acted on by ammonia, and the only way I can account for it is that the ammonia decomposed the gelatine to a certain extent, so altering the porous film with which the silver was surrounded that the change of colour was not due to a change of composition but to a molecular change in the silver itself. The yellowing in the high lights also leads me to think that I was correct in thinking that there is in an emulsion besides the haloid of silver, there is also formed a certain organic compound of silver and gelatine, which is insoluble in a solution of thiosulphate of soda, and it is this compound which also produces the yellowing when the prints are acted on by sulphurated hydrogen.

Another point with regard to the Eastman bromide paper which surprised me the other day was its extreme insolubility. I wanted some of the reduced silver for examination, and to get it exposed two pieces 1-plate size to light and developed and fixed in the usual way, only omitting the alum bath. To get the film freed from the paper I thought I would treat the sheet with boiling water. To my disgust (at the time) I found it had not the desired effect, and I had to scrape off the film with a spatula, and it was not until I had boiled it about a quarter of an hour that the scrapings seemed in any way to lose their form.

II. J. GIFFORD.

ORTHO-, ISO-CHROMATIC.

THE terms *iso-* and *ortho-chromatic* are rapidly becoming a part of our language. Would it not be worth while to stop for a moment and ask the question, Do they really mean what we generally suppose they do? I presume that by those words we mean the quality of rendering colours in the correct—i.e., proportional—order of luminosity.

Turning to my Greek Lexicon, I find,—(1), *Orthos* (adjective), straight; Latin, *rectus*, upright—metaphorically, right, safe, prosperous, upright, just; as an adverb, rightly, correctly, really, truly. (2), *Isos* (adjective), equal to, like, level; (adverb), equally. (3), *Chroma* (*a*), surface of the body; (*b*), colour (especially of skin—i.e., complexion); (*c*), metaphorically, ornaments, embellishments; (*d*), technical term in Greek music, a modification of the diatonic scale.

Turning now to my English Dictionary, I find these words used variously in composition,—e.g., (1), *Orthodoxy*, sound faith; *orthography*, correct spelling; *orthopterous*, straight-winged, &c. (2), *Isothermal*, equal temperature; *isomorphic*, same form; *isochromatic*, having the same colour.

Now with regard to *chroma* in composition, I do not find any which come under the meanings of (*a*) and (*c*); one under (*d*), namely, *chromatic scale*, a musical term; and under (*b*) we have many, namely, *achromic*, free from colour; *isochromic*, see above; *polychromatic*, many coloured, &c. From all of which I think we may safely draw the following conclusions, namely, (1), That *ortho* and *iso* neither in the Greek nor English use bear the meaning of *proportional* or *relative*; (2), That *chroma*, when used in this sense, is distinctly *colour*, and not *luminosity*.

Therefore *iso-* or *ortho-chromatic* do not mean proportional or correct luminosity.

Turning once more to my Greek Lexicon, I find *kairos*, due measure, right proportion; but with regard to luminosity, the idea seems to be distributed amongst several words, e.g., *phaios*, daylight; *euphegges*, clear bright light; and *lamprotes*, brilliancy. I therefore venture to propose *kairo-lamprotic* as being something nearer the meaning than *ortho-* or *iso-chromatic*.

It may be said, Why have a new word when we all know what the old terms are supposed to mean? So far as *isochromatic* is concerned, we find the Dictionary has already assigned it a meaning very far removed from that which it is generally supposed to mean; and regarding *orthochromatic*, it is simply misleading, and if left must be the cause of confusion hereafter. Therefore I say by all means let us try, so far as we can, to call things by their proper names.

I fully agree with the author (whose name I forget) who said, "Words are the tools of thought, and the best tools will yield the best work; therefore call things properly and you will the more easily think correctly."

We have quite a sufficient number of misnomers in our daily use to free us from any anxiety lest the curiosities of that class will shortly become obsolete.

FRED. C. LAMBERT, M.A.

ACCESSORIES OF THE LANTERN.

CHAPTER IV.—LINEN SCREENS.

LINEN screens are, for occasional exhibitions, the most convenient, as they are easily stretched and take up little space during travelling; when soiled, they are more easily cleaned than any other kind, as it is only necessary to wash them. They do not reflect quite so much light as a newly whitewashed surface, but the difference is not very great if the linen is quite clean and well bleached.

When choosing material for a linen screen, that should be selected that is the closest in the mesh and the most opaque. All light which passes through the screen is not only wasted, but also tends to fog the picture on the screen, being reflected from the wall behind the sheet. For screens larger than ten feet square, it will be necessary to join two widths together. In making a fifteen feet screen, a five-foot width may be sewn to a ten-foot width; the screen will then have a seam right across it five feet from one edge. When this screen is stretched for an exhibition, care should be taken that this edge is put at the bottom; the horizontal seam will then be hidden to some extent by the broken foregrounds of the pictures.

The effect of the joining is that of a white line across the disc; this is caused by the doubling of the linen, the light that passes through the first thickness (and which would be lost in other parts of the screen) being reflected back again from the second thickness, thus giving enhanced light where the seam is. This white line shows very prominently when it crosses a sky tint. It can be lessened by making the folded part very narrow, or the linen may be put simply edge to edge, as in carpet stitch.

It is a bad plan to sew a strong web or tape round the edges of the screen. The web often does not stretch as much as the linen, and then it is necessary to apply great force to get the screen free from creases. A screen should have the edges simply hemmed. At the corners a few inches of webbing may be sewn on so as to form an eyelet or loop—this will prevent the screen tearing when being stretched; also small eyelet holes, strengthened with a little webbing, may be inserted in the borders of the screen at intervals of two feet or so. I do not admire a fringe of white tapes all round a screen; they give an untidy appearance, especially when a few of them are missing from their places, they being very apt to be pulled off.

In order to avoid too frequent washing of the screen, one side should be kept clean; and as dirt must sometimes come in contact with the screen, owing to dusty walls, curtains, &c., not to speak of laying the screen on the platform boards, the dirt should always touch the side of the sheet that does not face the audience. This is easily managed by always folding the clean, or front side, *inwards*, after every exhibition. When letting down a large screen, the lower part should be drawn forwards to prevent the face of the screen touching the floor; when re-erecting the screen, the inner side (as it has been folded) should again face the lantern. By adopting this simple system, a great saving in trouble and laundry bills will result. In order to further protect the linen against dirt, it is a good plan to have a strip of calico, four feet broad and as long as the screen is wide; this calico should be spread on the floor, and the linen laid upon it when raising or lowering the screen. The calico is also useful to wrap the screen in.

The stretching of a linen screen is usually done by ropes or cords, with the aid of a wood frame of some kind. Some lecturers who constantly travel with the lantern content themselves with ropes alone, and do not carry any supporters. With the aid of ladders they drive large nails into the side walls, to the great detriment of the plaster, and hang the screen on these by ropes. But sometimes they come to a hall which has, perhaps, been newly decorated, and they are forbidden to put any screw or nail into either the walls or the ceiling, and sometimes even the floor is prohibited. As the person

who gives this information usually sits down and watches to see that these rules are not broken, they are then in a quandary, and have to call in the aid of a carpenter to arrange some support for the screen. Now, joiner's work is expensive. I once knew a master joiner commissioned to fix up a twenty-three feet screen in a large hall; the man made a day's work of the job for himself and two or three of his men, and charged 30s. for it. He did the work well, there was no denying, but he got no more commissions of that kind. Those who had engaged him contrived to stretch the screen themselves in future exhibitions.

Screen poles are, in my opinion, well worth the slight increase they cause in the amount of luggage carried. With these, a screen can be fixed up in any hall, without interfering with the walls or ceiling, and, if necessary, a couple of half-hundredweights can be made to do duty for screws in the floor. They save a good deal of trouble in doing away with the use of borrowed ladders, which are generally of a rickety and uncertain character, and either too short or too long. Imagine a gentlemanly operator, unused to feats of balancing, mounting to the top step of a wobbling ladder and leaning his person against the whitewashed wall to prevent himself falling over backwards, which gradually gives him the look of a miller; then he has to ferret out some joint under the plaster to drive his nail into, and after operating over a square yard of wall surface and detaching a quantity of plaster which falls into his eyes, he comes to the conclusion that the wall is composed of one solid block of stone without a joint; so he descends, hot and perspiring, and finds several people who have been watching him engaged in an heroic attempt to appear unconscious of the mirth that is consuming them within. Experience of this kind ruffles a man's temper, and renders him unfit, if he has to lecture, to do so with any approach to affability.

Frames are sold at some opticians, which form a complete square the size of the screen. They are well suited for small sizes, such as ten feet and under, but for large screens of fifteen or eighteen feet, a square frame would be too heavy and cumbersome. The horizontal rod at the top of the screen requires very strong side pieces to bear the weight; hence I think that top and bottom pieces should be omitted, and only side pieces used. These should be of course jointed. They may consist of laths three inches wide and one and a quarter inches thick, with bolt holes at intervals of six inches apart the whole length; a pair of ten-feet laths like these can be bolted to any height up to nineteen feet. Four of these will suffice for a fifteen or eighteen feet screen. I prefer, however, to use shorter pieces, about four and a half feet long and one and a half inches diameter, with pieces of brass tubing fixed on; these will join together like a fishing rod. The top piece may be thinner than the others, and should have a ring at the summit. Eight such rods will form two strong uprights, capable of supporting an eighteen feet screen, which is large enough for most halls. If necessary, the uprights can be further raised by standing them on chairs; if the hall is low, the height of the uprights can be diminished by omitting one of the rods from each. These rods are much lighter and more portable than the laths. When travelling they may be strapped together as a small bundle.

In answer to inquiries as to where white paper of considerable width, suitable for small screens, can be obtained, I may say that Messrs. Winsor & Newton, of London, supply cheap "cartoon" paper, sixty inches wide, at 1s. the yard. A similar paper of the same width and price, called "wide cartridge," is sold by Messrs. Goodall & Suddick, stationers, Leeds. A six-foot screen may be made by joining a strip thirteen inches wide on the bottom of the five-foot width, as a join in paper does not show so prominently as in linen. These paper screens are not very durable, and many will prefer to use a hand-made drawing-paper five feet five inches and six feet six inches wide, which is sold at 4d. per square foot by the Leeds firm. This paper is mounted on brown holland, and is of course much less likely to tear than the cheaper kind.

ALBERT WM. SCOTT.

ON THE USE OF THE STEREOSCOPE AND ITS SCIENTIFIC APPLICATION.

I.

THE accession of so much new blood to the photographic ranks ought, one would think, to give a fresh impetus to the use of this beautiful, but now almost obsolete, instrument, for there must be large numbers

now whose acquaintance with it is extremely slight, and to whom a study of its powers would be as a new revelation. With this hope, and the idea that an occasional paper may keep the thing green and act as a stimulus to some reader who may favour me with his attention, and because I wish to suggest a new sphere for its use, I venture to return to this old crotchet of mine and pen the few following remarks.

It is now generally recognised that the principal cause of the rapid decline of the instrument, in the estimation of the public, arose from the deluge of rubbish in the shape of articles called stereoscopes and slides which flooded the market. This badness of quality, combined with an absence of the slight cultivation necessary on the part of purchasers for fully appreciating the beauties of binocular vision, caused the reaction, which has resulted in the articles in question becoming old curiosities instead of contributing to the amusements and pleasures of home as during a somewhat short period in the past generation. If amateurs would but take the matter up in a hearty manner the question of lack of cultivation need scarcely arise, for each would be likely to make sure that his slides were viewed in suitable instruments to the best advantage, and take care to impress his friends in respect of how and what to observe. I should be sorry to see the matter gone into for purposes of commercial speculation, for I have an impression that the instrument even when good is a trifle beyond the general public, and therefore if it became again common it would only be as a sort of fashion to be followed by mere imitators, which would pass away and leave the feeling usual to things of so fleeting a nature.

Some years ago I had exceptional facilities for ascertaining what power people were possessed of, and of judging by their remarks and conversation what they expected to see and what they really saw. The firm who employed me had a large stand located in a prominent position in the Crystal Palace for a number of years. This was constructed to carry twenty-four stereoscopes fitted with whole achromatic lenses of about one and three-quarter inches in diameter and six inches focus, of Dallmeyer's best make. The instruments and slides were arranged as perfectly as it was possible at that time to make them, and as everything for exhibition purposes must be fixed and unalterable, the details of focus, width between centres of lenses, and corresponding width between the centres of each half composing a stereoscopic slide, were calculated for nominal sight. Each instrument was what a popular one should be. Its value as an attraction more than equalled anything in the building, for peep-holes will cause any one, rich or poor, small or great, philosopher or fool, to gravitate to such mysterious places, eager to know what is on the other side, so there was no lack of subjects for study. Besides the stand, there was a stall with an assortment of instruments consisting of good, bad, and indifferent specimens of the combined arts of the optician, cabinet-maker, and tinman, the work of the first-named in many instances ceasing, I suspect, after he had parcelled up the lenses in dozens or by the gross to be sent to members of the latter handicrafts to select and fit up into the finished article. The collection here fairly represented that of a London stock house, and afforded opportunities for judging of the effect of a bad instrument on an intelligent person.

Of the observers, a large proportion might be at once dismissed, because they could see better with one eye the expedients adopted to ensure to them the full enjoyment; for their supposed advantage of single vision were sometimes amusing, covering the eye with the hand, the corner of a shawl or pocket-handkerchief, being quite as frequent as squinting, which did not appear as common as might have been expected. Many proclaimed the visit to be their first acquaintance with this kind of thing by peering into the second eye-piece, and expressing some dissatisfaction because it was the same. This obtuseness, I believe, was not due to any instrumental defect or of sight, but purely to want of power to see anything more of the third dimension of an object than was apparent from its light and shade, no other illusion being looked for; the mind probably failed to perceive this, and would require a remedy, a little cultivation by such means as would be found in dissimilar pictures of simple geometrical figures, in which the simple idea of solidity would be produced without other complications, being more suitable. Many others saw double, a sort of after-dining-out vision. This undoubtedly pointed to unsuitability of instrument slides, the lenses or pictures being mounted too wide apart for such persons to make the two halves of the slide coalesce

without considerable strain and discomfort. A few of this class may swell the ranks of the one eye observers, but others of more intelligence would probably consider it an inherent defect of the stereoscope, and have nothing further to do with it. Another class, smaller in number, found it necessary to wipe up the lenses or to rub their eyes. They could not see the pictures clearly, probably because the lenses were not quite suited to their somewhat abnormal vision. As we used the interior of the stand as a room, one was able to note the remarks of the sightseers, and these bore out the conclusions drawn from observations made outside, namely, that a very large percentage of the visitors were not quite comfortable, or had the power to appreciate what was before them. If with the good stereoscopes of the stand so many failed to see aright, one may feel assured matters were not improved at the stall adjoining. Here the things were made to sell, and were got up more pretentiously. Elegant brasswork, open tops of splendid designs, choice veneers, and French polish, were the most prominent qualities, and very tasteful and pleasing some were in respect of exterior. Had their optical arrangements only been equal to this external get-up, there would have been less to find fault with, but it was just in this most important detail that so many failed.

In going through a consignment I have frequently found considerably more than half of the instruments possessed of some defect in this respect, especially in the class having prismatic lenses in small eye-pieces. It was not at all uncommon to find these mounted with their thick edges together, or obliquely to one another, which would be a fatal defect to any one not understanding the principles of the thing, it being quite impossible to see anything but double in them. The commoner forms, with large unachromatised prismatic lenses, were far preferable and more fit for popular use than the more expensive sorts. With the better class of English make the case was different. They were not turned out in shoals like the foreign ones and other common kinds, but were fitted up intelligently and well. Had their price been less, they might have saved the reputation of the stereoscope and prevented it from being cast aside.

In respect to the slides, I do not believe they were much to blame, their prevailing faults being but minor ones, and such as would scarcely add to the difficulty of perceiving stereoscopic effect without strain or discomfort if viewed in a good instrument. The principal were those of mounting the pictures too far apart, and of cutting both halves alike, instead of showing more subject in each half at the edges which come together in the centre than the corresponding edges of each at the outside. When they are both cut alike, the rather unpleasant appearance of the picture showing in front of the mount becomes visible. Cutting them unsymmetrically prevents this, and does not curtail the size of picture, and if a distance of two and three-quarter or two and seven-eighth inches be fixed upon as the amount of separation between two corresponding points in the foreground of either half of the slide, and both pictures be mounted truly parallel to one another, there will be no cause to blame the slide if double vision result.

The difficulties of getting negatives for the purpose under the present circumstances of easy photography being but slight compared with those of the old collodion days, the amateur has a fine field before him. Subjects are now possible that could only be dreamt of then, and I feel persuaded that any gentleman who devotes himself to this branch of photography, and prints his negatives as transparencies, will derive more pleasure from it than if he were to confine himself to paper work, unless this were of large size; and as the printing processes are so numerous, and capable of producing a great variety of effects, it is possible to represent nature in nearly all its aspects. The rendering of texture, surface, and lustre, as we see it, can only be done by binocular pictures, a single one being nowhere in comparison. Let any one who questions this statement make a stereoscopic photograph of a glass of water, or a piece of plate, print a transparency, and study it in and out of the stereoscope. He will need no further argument, but will admit that sheen and lustre, as represented by single specimens of paper work, are dull and spiritless to a degree he never imagined. The negatives produced for the one purpose would be quite as serviceable either for lantern work or enlargement, so his practice could be diversified with either of these at will.

As the plea for the use of the stereoscope as a scientific instrument will make this article too long, it will perhaps be better to break off here and leave its discussion to another paper. JOHN HARMER.

THE EDUCATION OF THE CHILDREN OF PHOTOGRAPHERS.

THAT a public controversy should ever have arisen dealing with the relative positions of amateur and professional photographers, seems to me much to be deplored; before it began we were all jogging along pleasantly together, and questions tending to promote differences had better have been left untouched. Amateur and professional photographers are living facts, neither can abolish the other, nor should have any desire so to do; such a feat being impracticable, it was unfortunate for all of us to see the unnecessary introduction of a new discord, tending to create a division of forces where all should pull together. Bitter and unjustifiable words were uttered by exceptional individuals on both sides of the controversy, and each side seemed to think it had some inherent superiority over the other, but was unable to give evidence thereof. Suppose a man to be an amateur photographer, and nothing else, giving time to the subject only now and then, he ought to be sorry if his idle pastime does injury to any professional photographer leading a more noble and honourable life, that is to say, industriously doing steady work for the world day by day, and having a moral right to existence because he regularly gives to society an equivalent therefor in duties performed. A man who goes down to his grave after a life during which he has received ten or a hundred more benefits from the world than he has given to the world in return is a sorry spectacle; it would have been better for human kind had he never been born. What right has he to consider himself the equal of one who does his duty in life, and whose existence is a benefit to the community? In examining this question from another point of view, let us take the case of an exceptional photographer with no soul above that of the love of the most contemptible of vices—the love of making money; I mean a man who makes no new researches nor any attempt at self-cultivation, but who lives the life of a vegetable, following the dull routine of the trade he was taught in his youth, and getting angry when the work of some amateur in his neighbourhood interferes a little with the flow of pollard into his trough. All the practical advantages are on the side of the professional photographer; he is at the work from one year's end to another, yet if an amateur can step in and beat him upon his own ground by a more refined taste and a greater love of science, such a professional deserves to suffer, assuming amateurs to injure commercial photographers as proved by a broad view of the facts rather than by a few isolated examples. The popularity of music and singing, and the great number of amateurs connected therewith, do not seem to injure professionals; the amateurs widen and keep alive the interest in the subject. The same may be said in relation to professional and amateur artists with the brush. It is a difficult question, no doubt, but I have carefully watched the influence upon the profession at large of the action of some of my personal friends as amateur photographers; in the course of two years they spent about one hundred pounds in dabbling in the subject—had their likenesses taken by several leading professionals to see how they arranged sitters, and so on, then grew tired of the pastime and dropped it. Had they not turned amateur photographers they probably would not have spent five pounds among photographers and photographic dealers in the same time.

As Dr. Vogel says, only those photographers who are unable to do work of sufficiently high quality are likely to be injured by the amateur. One class of such inefficient photographers I think deserves sympathy; there may be a man who loves his work, and improves it and himself as much as he can, yet is unable to compete in quality of work with the amateur when the latter chances to have a more cultured taste and a higher education. Education is, at the present day, what a spear is to a savage; it is a weapon of offence and defence in the fight for ascendancy in life, and, just as among savages, conquerors disarm captive populations, so, in more civilised communities, do educated persons who live for selfish purposes desire to keep the many ignorant to use them for their own ends. In a workshop the best-informed man inevitably gets an ascendancy over his companions in labour, and so is it with larger communities; the best educated nation in the world will become the most powerful nation in the world, assuming all other conditions to be equal. Hence I say that it is hard upon a professional photographer, who has tried to improve himself to the best of his ability, if he is accidentally commercially injured by the work of an amateur who had started under more favourable conditions in life, and the best plan for the photographer is to take care that his own children shall start better armed than he himself was in the social battle. It is better to give the children a first-rate education than any amount of money. There is no more painful object in creation than the son of a man who has had but one object in life—that of making wealth by exacting all he can from his neighbours. The son has some of the unpleasant hereditary

characteristics; he is above the necessity of making himself an industrious shopkeeper like his father; he thinks that his money will carry him into refined society in which such a snob would be unbearable, and is astonished to find that cultured people with no wealth at all cannot help holding him in contempt; he will not associate with his own kind, so no course is open to him but to jog along steadily to the Devil; we have all seen him on the journey.

The best thing then that a father can do for his children is to give them a good education, including one or more of the fine arts, and to start them in life with a store of mental resources of which no earthly power can deprive them. Here comes the most practical part of my sermon. Great Britain is notorious on the Continent as being, with Spain, one of the most uneducated countries in Europe. Education here is the privilege of the very few, and almost absent among the many. A great outcry is made against the expense of the trifling beginnings of education forthcoming in Board schools; what would such objectors say about Switzerland, in which country one-third of the whole national revenue is spent upon education? In our own country the expenditure is but five per cent. of the total national revenue. The fact is, that upon an average a much better education than in England can be obtained nearly everywhere upon the Continent, and at perhaps half the cost, so I would recommend photographers to send their children abroad to get that education which they cannot obtain at home, unless at comparatively very expensive rates; this plan is extensively adopted by persons of limited means in English society.

Once, in mooted ideas like these to a photographer, he responded, "Well, where do you advise me to send my son, not too far from London, and where the people speak French?" There are plenty of first-rate schools in Paris and Brussels, more or less used by the English, but there are parents who prefer quieter localities. Boulogne-sur-Mer, so very close to England, is not a desirable place; it is half Anglicised, and one might almost as well settle in Brighton. Calais is flat and uninteresting, but at Guines, a few miles out, near the Field of the Cloth of Gold, are some schools much patronised by the English. Altogether, I think Ghent about the best place near London to which to send boys and girls to be educated; sometimes English families settle there for a few years with no other object than that of enabling their children to get a first-rate education at small expense when compared with English charges.

Ghent prides itself upon its educational position, and claims that its free schools "have a European reputation." They were founded as early as 1828, at which time three of them were established, but in 1837 their number was increased to eight, in consequence of the intelligence and generosity of the Burgomaster, M. Joseph Van Crombrughe, one of the most far-sighted men in Europe in his day, and whose name is now venerated in Ghent. At the present time there are a great number of schools of all classes in Ghent, and the city is richly dotted with the fine public buildings devoted to scholastic purposes, including some for giving thoroughly practical education in the arts and sciences. The Municipality of Ghent now expends upon its public schools about £40,000 a-year, scarcely any of which goes to pay rent, since, on the Continent, very much to the welfare of its inhabitants, scarcely a public building of any value can be found erected upon another man's land; houses and the land they stand upon are usually sold together, and I was told in Ghent that probably the whole of the cotton and other factories in the city are built upon what we call freehold land; any fabricator who did otherwise might be looked upon by his friends as a lunatic. Ghent is quickly and comfortably reached from London or the north of England *via* Harwich and Antwerp; in fact, the comfort and the moderate rates for dining and passage on board the Great Eastern Railway Company's steamers are beginning to be recognised by the frequenters of the more expensive and exclusive routes to the Continent. The steamers pass the terminus of the little local line from Antwerp to Ghent, half a mile before they land the passengers at about ten o'clock in the morning in the former city, so the visitor has but to go a little way back along the quay, where the railway steamboat conveys him to the other side of the Scheldt, and in an hour or two he is in Ghent, the chief seat of the cotton spinning industry of Belgium. He might go by one of the large State railways from Antwerp, but that route is a long way round.

My idea is that the photographer of to-day should train up his children to be able to better compete than himself with the amateur in photography or in any other profession, by sending them abroad to receive an education they cannot obtain on equally moderate terms and with equal fulness at home. The large numbers of young men and women leaving Continental universities and technical and other schools to do their work in the world, can, of course, compete with the English with success, and deserve so to do, because they have

gained the power by their own industry and by the enlightenment of the governments under which they live. Hence orthochromatic photography comes from abroad, and the photographing of the pictures in the National Gallery and Windsor Castle falls into the hands of a foreign firm; also, photo-mechanical printing has attained a perfection unknown here, as proved by the specimens exhibited to the Photographic Society of Great Britain by Mr. Warnerke. As regards technical education, I would recommend that the children of photographers be taught the art of painting and the sciences of chemistry and optics; art education should take precedence, because the photographer who has it not is but an intellectual mechanic, and can never occupy the highest positions in the profession hereafter, for the cultured section of society is beginning to clearly distinguish between those photographers who are artists and those who are not such. The young photographer, armed for the battle of life as herein suggested, should irradiate his educational acquirements with the fire of genius, and be able to seize each occasion as it presents itself; for instance, when Captain Abney acted upon his magnificent idea of nominating a variety of corpses to serve on the Council of the Photographic Society of Great Britain, the young fledgeling of a photographer should have arranged his models with prophetic instinct, and given us an ideal photograph of the Council of the future, with a jolly old corpse in the chair, keeping order by hammering the table with a thigh bone. No sensitive soul should feel grieved at my use of the word "jolly," although some inartistic person has begun to murder the good old song—

"For he's a jolly good fellow,"

by altering it to—as sung at the Glaisher testimonial dinner—

"For he's a hearty good fellow,"

thereby taking real heartiness out of the expression, and mutilating time-honoured tradition. The mutilator must have been a sentimental hairdresser or head footman, who knew where to draw the line in points of refinement, or he may have been the publisher who received from a celebrated literary man the following couplet in a book for children—

"There was an old woman as ugly as sin,
Who lived upon lucifer-matches and gin."

The publisher struck out these lines as unsuited for his highly-refined taste and customers, and, without permission, substituted something of his own, utterly vapid and uninteresting. He was no doubt astonished when the *Athenæum* newspaper fell upon him hotly for his impertinent vulgar refinement.

W. H. HARRISON.

PHOTOGRAPHY IN THE FIELD.

[A Communication to the Photographic Society of Chicago.]

As our Society includes both professional and amateur photographers, and as there is a general idea that the professional takes but little interest in landscape work, a paper on photography in the field may be, by some of you, considered a mistake, as applying only to one section of the Society.

It will be readily admitted that there are few trades or professions that are more exhausting, both mentally and physically, than that of a fully employed portrait photographer, and no one needs more than he an occasional period of relaxation and recreation or change of employment. Now it will be evident that if that necessary change of occupation can be in any way made conducive to the improvement of the photographer's ability as an artist, his period of relaxation will be a double gain. I have, in my time, tried many methods of making "happy holiday," and in company with almost all classes and conditions of men, including many hard-wrought professional photographers, and believe that the pleasures and advantages of all the others put together do not equal those derived from the judicious practice of photography in the field, or landscape photography.

Mr. Enoch Root, in a recent number of the *Philadelphia Photographer*, says: "The constant routine of the studio is not favourable to art progress," a statement that I think a little too strong, but I heartily endorse the recommendation which he founds on it. "Therefore let the gallery artist shake off, from time to time, the daily cares, and go forth to outdoor nature with his camera, and enjoy the pleasures of an amateur in the true sense of that much misused term. From such an excursion the participant will return refreshed in mind and inspired by nature's charms to an incentive for the production of better work, in the no less artistic but less fascinating field of portraiture."

Landscape photography, then, ought to be equally interesting to the professional and the amateur, and as the processes and appliances by which it is carried on have reached a degree of perfection not even dreamed of little more than a dozen years ago, there is hardly any excuse to be made for the man who makes a photograph but not a picture.

To those who have but recently joined the ranks, a slight sketch of what photography in the field implied a quarter of a century ago may not be without interest, and as a personal reminiscence of one of the

periodical (generally weekly) trips of the Edinburgh Photographic Society may be taken as a type of the average of such outings, I give it as it presents itself to my mind at the present time.

It was a Saturday morning, early in the sixties, and about the time the corn was in the ear. I don't, of course, mean maize, to which that name seems to be universally applied on this side, but oats, which the great Dr. Johnson characterised as "in Scotland food for men, and in England food for horses," an observation which elicited, doubtless from some observing Scotchman, the reply: "And where will you find such men, and where such horses?" I reached the railway station with a cab load, consisting of the following items:—a 11×9 brass-bound camera, weighing twenty-one pounds, and meant to last for all time; it is now over thirty years old, and is, or was two years ago, as good as ever. A water-tight glass bath, in wooden case, holding over ninety ounces of solution, and weighing twelve pounds; a plate box with a dozen 11×9 plates, weighing almost as many pounds; a box 21×18×12 inches, into which were packed lenses, chemicals, and all the hundred and one articles necessary for a hard day's work, and weighing something like twenty-eight pounds. The advent of folding tripods had not come, at least folding tripods that were rigid enough for such large cameras, and so I had perforce to encumber myself with one that, when closed, looked like an alpine stock, over five feet in length and much thicker than my wrist. It weighed about five pounds. Lastly, there was the tent. Of those I have had various forms and kinds; my favourite was known as "Smart's," a beautiful arrangement of angled spars, covered with heavy black cloth, that made a most convenient dark room, about 40×40 inches, and 6½ feet high, with ample table accommodation; the whole packed into a leather case, like a long roll of bacon, and weighed over forty pounds. I was soon joined by a dozen or so of others, similarly equipped, although in some cases with heavier loads, and in due time we started for our destination, Arncliffe, some twelve or fifteen miles from the city. With a load of about 120 pounds, even although shared by an unlucky friend who had been impressed into the service, and, of course, promised copies of all the pictures that should turn out well, we did not care to walk far, and, of course, where the tents were set up, there or thereabout the whole work of the day had to be done.

Now, if you will bear in mind that after a suitable spot had been selected, tent pitched, water supply secured, and everything ready for work, the real anxiety of the day began. The bath was in good working order last night, but how will it be to-day? Baths were often the most obstinate and contrary creatures in existence, and seemed to take especial delight in taking the snails just when they ought to have been on their best behaviour; while collodion, as if recognising the fact of its importance, was as contumacious as an Irish pig, and uncertain as—well, as Chicago weather. The production of a sensitive surface with material so uncertain in its action was, certainly, not conducive to that frame of mind so necessary in the communing with nature, to wile her into putting herself into her most artistic aspect; and as the surface, once prepared, had to be used within a few minutes thereafter, there was no time to wait for the disappearance of a scowl caused by a passing cloud, and she had to be taken as she was rather than as she ought to have been.

By-and-by, thanks to Tapenout, Hill Norris, Fothergill, Major Russell, and many others, who showed us how to prepare a dry plate that would be always ready when wanted, our labours were lightened, and the possibilities for good and comfortable work vastly extended; but the long exposures, that varied from fifteen minutes to almost any length of time, including, on one occasion, from a Saturday afternoon to a Monday morning, in the case of an interior of the old Antiquarian Museum of Edinburgh, rendered such pictures as are now most frequently produced and most generally admired, simply impossible.

If we contrast those days with the times in which our lines are cast, we will be able to realise how great is the gulf that is between them, and while congratulating ourselves on our more favoured position, will, I hope, not forget that to whom much is given of them much will be required. Under the older and less favoured circumstances, to aim at technical perfection was about all that could be expected of us, and we need hardly be ashamed to confess that when our photographs were picturesquely beautiful, as well as technically perfect, it was more owing to chance than good guidance.

Now, however, with apparatus of the most perfect construction, and plates or paper films as reliable as a sundial on a summer day, and both as light and of as little bulk as a preacher's valise on a Saturday to Monday visit, we are expected to reproduce nature, not exactly as she is, but as she ought to be; to, in fact, produce such pictures as shall for ever shut the mouths of those who deny to photography the right to rank as a fine art. But this cannot be done without systematic work, involving much careful forethought. In the first place, the very simplicity of the operations and perfection of appliances militates against the high standard that ought to be aimed at. In consequence of the convenience of double plate holders, or the even more convenient roll holder, the landscape photographer is tempted to take with him to the field a number of plates or films far in excess of what it is possible to convert into really artistic negatives during the few hours that are available of even the longest day for good work; and as plates and films are now so cheap, he is tempted to make exposures on subjects and under conditions that yield negatives that are hardly worth the trouble of development, and that are rarely subjected to the ordeal of printing. Half a dozen negatives that are both

technically and artistically satisfactory, are surely better than half a gross of such as are too frequently taken, simply because we dislike to bring home clean plates; but the good old couplet,

"He that fights and runs away will live to fight another day,"

ought to be kept in mind, and as both films and plates will keep, a new golden rule should be formulated and rigidly enforced: *Never make an exposure unless under conditions that offer a fair probability of producing a satisfactory picture.*

How are those conditions to be secured? Simply enough; never take your camera to unknown ground. Just as six perfect pictures are better than six dozen mere photographs, so are, as a rule, six negatives that have been prospected for on one day, and exposed on another, better than the same number that have been selected and exposed at the same time. My ideal of a photographic outing is one that shall occupy two days. On the first, the camera is left at the hotel or place of residence, and with a compass, a strong knife, a pretty long walking-stick with a crook at the end, and a supply of twine, I go over the ground in search of the picturesque. The ability to recognise material that has the making of a picture varies vastly in different individuals, but rapidly improves by cultivation. When a suitable subject is recognised, it should be examined from all possible points, with the view of selecting that from which the principal lines fall just where they should, and where the foreground will be satisfactory without interfering with the proper position of the horizon. Intervening branches may be cut down, or turned out of the way and tied up if necessary; and even scrub and brush may be created and made to wonderfully improve the composition by sticking branches into places where they seem to be required. Lastly, the all important point of shadows must be considered. The artist must decide as to where they will be most effective, and ascertain by the compass at what hour they will be there, and so be able to return on the following day and make the exposure without further trouble.

It is true that the true artist is a law unto himself, and no really high-class work is ever done by those who tie themselves down to hard-and-fast lines; but there are a few leading principles which even the greatest artist rarely if ever neglects, and the recollection of which will greatly help the inexperienced to secure at least tolerable results.

I have brought a few specimens of various classes of pictures, and if our friends at the lantern will light up and pass them through, we shall see the advantages and disadvantages of attending to, or neglecting those first principles.

Our first picture, as you see, is not a picture, but a sheet of clear glass with two lines crossing in the centre, and dividing the plate into four equal parts. Now the weak parts of a picture are those covered by the lines, and the weakest is just where they cross. Nothing of importance in a picture should be placed on those lines, and especially on the weakest part—where they cross. The strong points, that is the points on which the principal objects should fall, are below the horizontal line, and about one-third the distance to the right or left of the perpendicular line, and the points next in strength are corresponding places above the horizontal line.

The next picture is intended to illustrate the necessity of giving attention to the horizontal line. That line naturally is always on a level with the eye of the beholder, no matter at what elevation he may place himself, and in a picture, under ordinary circumstances, should be arranged so as to lie about one-third from the bottom, or where that is impossible, then about one-third from the top—never, under any circumstance, in the centre, or place of the horizontal line in our first illustration. Here we have a fairly well composed picture, in which the lines are properly balanced, and the bridge with the fishermen, which is the principal object of interest, just on one of the strong points. The horizon is, however, so much too high as to convey the idea that the river runs up a tolerably steep hill, instead of through a comparatively flat gorge in the landscape.

The next is a single yacht in full sail, technically a very fine photograph, but utterly absurd from the position of the horizon, and the consequent large foreground. The water is really represented as an inclined plane. If we now, by this card, cut off the foreground, we at once bring the yacht into its proper position, and by apparently lowering the horizon, the water at once appears as a level surface. This, our next picture, is a similar seascape, with a single yacht, also in full sail, but in this case the camera has been level; the horizon is exactly one-third from the bottom of the picture, and the composition is just as it ought to be.

Our next picture is copied from an engraving after a celebrated artist. The object is the old mill and cluster of houses in the strong point at the left of the centre line. The small clump of brush and stunted tree on the extreme left, may to some seem unimportant, but their value will be apparent if we cut them off by a slip of cardboard. You see the composition is now lopsided, and there is a feeling of instability in the trees on the right. Even the way in which the small tree is bent is important as repeating, but in an opposite direction, the lie of the larger mass on the opposite side, giving thereby a faint but sufficient indication of the favourite pyramidal form. Of course the artist of the brush and canvas has many advantages over his brother of the camera; but when the latter overcomes those drawbacks, and produces pictures in spite of them, he is surely entitled to all the more credit.

The rest of the pictures are intended as examples of both good and bad composition, but I shall not detain you by a lengthened description of each. Every picture should have a motive or principal object, and all the leading lines and lights and shades should be so arranged as to lead the eye to it. As a general rule, only one principal high light is admissible, and the shadows, or the heavier of them, should lead the eye out of the picture. It is also a matter of much importance that the picture, or that part of it which is visible, should be sufficiently far from complete to suggest much more than is actually seen.

But I fear I have already occupied too much of your time, and shall conclude with the advice which has been repeatedly given, as an aid to securing pictorial effect. It is to select a title for each picture before finally deciding on its composition, and I know from experience that where there is a good title to work up to, the pleasure will be greater and the work easier.

JOHN NICOL, PH.D.

DARK ROOM ILLUMINATION.

In a recent number of the *Bulletin*, the subject of dark room illumination was discussed. From some experiments made by the writer, he inferred that an erroneous statement was made, at the January meeting of the Photographic Society of Chicago, in relation to the Roche glass for dark rooms.

I believe all agree that a gelatine emulsion plate is least sensitive to the red rays. Hence any coloured medium which, when examined with a spectroscope, transmits other than red rays is unsafe; and as between two fabrics, transmitting an equal amount of light, the one which absorbs or intercepts everything except the red of the spectrum is greatly to be preferred. It has frequently been stated by both English and American writers, that because the eye is most sensitive to yellow, it is the kind of light to use for the dark room, the inference being that we see just as well with only a fraction of the red light necessary for the same purpose. Now, unless the relative actinic effect of the two kinds of light on an emulsion plate is taken into account, the argument is of no value whatever. Some months since I attempted to determine the relative sensitiveness of emulsion plates to yellow and red light, and for this purpose chose the cloth known respectively as cherry and golden medium. As the cloth was similar in texture, and differing only in colour, I presumed the same amount of light would pass through each, although for the purpose of the experiment this condition is not essential.

The source of light was a sperm candle, placed either in a lantern or outside my dark room window. The seeing qualities for the two kinds of material was ascertained by examining a negative by looking through it, and also by reading printed matter. For these particular specimens of cloth the ratio, determined from a number of experiments, was as one to four and a half in favour of the yellow. Fraunhofer found the maximum luminous intensity in the yellow about ten times as great as at the C line. Comparing the luminosity of the whole area covered by the red and yellow respectively, the resulting ratio would perhaps be reduced to one-half the maximum. In other words, using yellow light we can see with about one-fifth the amount of red light required for the same purpose.

A Cramer lightning plate was exposed in my sensitometer at one foot distance with the following results:—

Golden medium, equivalent exposure one second; cherry medium, equivalent exposure twenty-eight seconds. In other words, the plate was twenty-eight times more sensitive to the yellow light than to the red. Combining the two results, so that the ability to see should be the same for both red and yellow, the final ratio is one to six in favour of the red as a protection to the plate.

In the same experiments, deep red glass was also tried with the same plate, giving an equivalent exposure of one hundred and eighty-seven seconds. The time then required to fog, using a sperm candle at one foot distance, was for the three media respectively, as follows:—

Golden medium	1 second.
Cherry medium	28 seconds.
Deep red glass	187 "

The deep red glass which I use, when examined with a spectroscope, virtually cuts off all except the red. The cherry medium, on the contrary, lets through a large portion of the yellow and green, while the golden medium extends the spectrum still further.

The Roche glass lets through most of the yellow and green—in fact the spectrum is almost identical with that given by the cherry medium.

A good deal of the ordinary red glass used by photographers gives a spectrum similar to the cherry medium, and is of course unsafe. A specimen of this kind of red glass, however, when compared with the Roche, was found to transmit more than twelve times as much light as the latter. Hence the apparent protection Mr. Roche and others have obtained is due simply to a reduction of the light and not to any peculiar non-actinic properties possessed by the glass.

Having made a very large number of experiments with various kinds of glass, cloth, &c., I would recommend the deep red glass mentioned above. Such glass is upwards of one hundred and fifty times more effective with a given light than the yellow cloth, and is the best medium for dark room illumination of which I have any knowledge.

PATENTS COMPLETED.

AN IMPROVED METHOD OF PRODUCING PRINTING SURFACES BY PHOTOGRAPHY.

No. 5205. EDWARD WILLIAM FOXLEE, 22, Goldsmith-road, Acton, W., Middlesex.—*April 14, 1886.*

My invention relates to that method of producing photographically engraved plates for intaglio printing, known as the “Waterhouse Process.” This process is described in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, and in the *Photographic News* for November 26th, 1880. Briefly, it consists in producing a photographic image in gelatine on a silvered copperplate after the manner of carbon printing. Then, while the gelatine is still wet, it is dusted over with powdered glass, sand, emery, or other gritty material, which has previously been treated with wax, stearine, or other similar substance. After the gelatine is dry, the gritty particles, which have imbedded themselves in it, are removed by brushing or other mechanical means. The grained image thus obtained is then treated with plumbago and an electrolyte made from it. This electrolyte forms the printing plate from which impressions are obtained in the copperplate press. In practice it is found very difficult to remove the gritty matter without injuring the delicacy and sharpness of grain it has produced, and it is the crispness of this grain that gives the ink-holding property to the finished plate. Further, if any of the gritty particles remain in the gelatine, they destroy the evenness of the grain and interfere with the deposition of the copper in the electrolytizing operation.

My invention consists of substituting for the powdered glass, sand, emery, or similar materials, which have to be removed mechanically, powdered resins, resinous gums, asphaltum, and analogous substances, which are insoluble in water but soluble in suitable menstrua, such as alcohol, ether, benzol, naphtha, turpentine, mineral oils, &c., according to the resins or resinous gums employed. In my improved method the grain-producing material is removed from the gelatine film by solution instead of by mechanical means, so that risk of injury to the grain by abrasion is avoided.

My invention is carried out as follows:—An image in pigmented gelatine, from a photographic negative, is developed upon a copperplate, either silvered or otherwise, by the usual process of carbon printing. After the print so obtained has dried, I sift over it a resin or resinous gum in a more or less fine state of division, according to the grain required, and then allow it to dry. The gelatine image may next be rendered insoluble by immersing it in a solution of alum, sulphate of alumina, or their analogues, and again dried, or the gelatine may be made insoluble by treating it, while still wet, and before applying the grain-forming material, with one of the alkaline bichromates, and, after drying, exposing it to the action of light. When the gelatine has been made insoluble the plate is immersed in a solvent of the resin or resinous gum employed. Thus, if sandarac be used, then I prefer alcohol as a solvent; if dammar or bitumen, benzol, and other resins or resinous gums, according to their solvents. After the resin has been dissolved the plate is further rinsed with the solvent and dried. The gelatine is then coated with plumbago and electrolytized in the ordinary manner.

Having now particularly described and ascertained the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is:—The use of resins, resinous gums, bitumen, and similar substances, which are insoluble in water, for producing a grain on the gelatine image, and afterwards removing them by solution, substantially as described, in place of the sand or other gritty matter hitherto used, and which has to be removed mechanically.

IMPROVEMENTS IN THE USE OF PARTIAL BALL AND SOCKET JOINTS FOR THE ADJUSTMENT OF PHOTOGRAPHIC CAMERAS ON THEIR LEGS OR STANDS.

No. 5626. CHARLES PUMPHREY, Regent Works, Herbert-road, Small Heath, Birmingham.—*April 24, 1886.*

ONE form is that of a hollow cup with rim or flange which is attached to the camera; the outside of the cup rests in a ring on the top of the stand. A circular plate inside the cup is the head of a screw, which by means of a nut secures it firmly in any position.

Another form is that a nearly complete sphere, is made part of the top of the stand, and this is grasped by means of one or two screws between two partial sockets, one of which need be only narrow, the other must be extended so as to be attached to the camera, and if that attachment is at an angle of about forty-five degrees the adjustment from horizontal to perpendicular is easy.

What I claim is:—1. The plan of using a hollow cup of the form of part of a hollow sphere, and grasping it between the inner and outer surfaces. 2. The use of such forms of annular or partial sockets as I have described or drawn to grasp a sphere which is attached to either a camera or in any position to the head of the stand.

AN IMPROVEMENT IN PHOTOGRAPHIC CAMERAS.

No. 6013. VERO CHARLES DRIFFIELD, Mount Pleasant, Appleton, Widnes, Lancashire.—*May 4, 1886.*

My invention is applicable to such photographic cameras (generally known as detective cameras) as consist of two distinct but connected cameras fitted with lenses of equal focal length, and which I shall hereinafter call duplex cameras. One of these cameras is used for focussing the image, and the other for the exposure of the sensitive plate.

My improvement consists in the application to the focussing camera of a mirror set at a suitable angle, or of a reflecting prism whereby the image may be seen from above. The mirror or prism may be placed behind the usual vertical focussing screen, or a horizontal focussing screen may be employed if the mirror or prism is placed below the focussing screen.

By this improvement I enable the operator first to support the camera steadily against his body during exposure of the plate, and at the same time to see perfectly the object he is about to photograph, and secondly to secure pictures without attracting the attention of bystanders or of individuals who may be photographed.

What I claim is:—The application to duplex cameras of a plane reflector or mirror for the purpose of rendering the image visible through an aperture in the upper side of the camera, substantially as hereinbefore described.

IMPROVEMENTS IN PHOTOGRAPHIC CARRIERS AND APPARATUS RELATING THERETO.

No. 16,605. HENRY COPPIN, 39, Wood-street, London.—December 17, 1886.

This invention has for its object to render photographic apparatus more portable and convenient than hitherto by reducing the bulk and weight thereof, and also to afford increased facilities for taking a series of views by providing ready means for using any number of plates with only a single back, thus combining efficiency, economy, and convenience.

To carry out my invention I make the frame of the camera back single, with a slot in the top through which to insert the carrier and plates, instead of double or book-like, or as a single frame wherein the carrier and plates are inserted on each side; and I furnish its two sides on their inner edges with grooved guides and grooves. These grooves are continued round the inner edge of the bottom of the frame, and serve to carry the ordinary hinged sliding panels, used for admitting or excluding the light, to or from the plates. A suitable opening is formed in the top of the frame through which to insert the carrier into the grooved guides.

Such carrier consists of a single frame of any suitable size and of sufficient thickness to take two plates instead of one only as heretofore. It is provided with the ordinary cross wires and buttons, which serve to secure the plates in position when placed therein.

By this improved construction of camera back any number of plates may be used with only a single back, while, owing to this and also to the carrier taking two plates instead of one only, numerous plates can be readily carried by the operator, thus greatly increasing its facilities for taking a series of views.

Another advantage of my invention is that the operator can readily change the plates in daylight by placing the top of the back in a light-tight bag fitted with an elastic nose or its equivalent, which serves to confine the mouth of the bag tightly round the frame of the back, and carefully inserting the carrier and plates therein or withdrawing them therefrom as required.

It is obvious, therefore, that owing to a single back being sufficient for any number of plates, and also to the convenience afforded by my improved double carrier in conjunction with the light-tight bag, the weight and bulk of the apparatus is considerably reduced, and increased convenience and economy are obtained.

My invention is readily applicable to existing camera backs, and to camera backs so made, by screwing or otherwise fastening the two frames together so as to form a single frame, and fitting the same with grooved guides so as to carry my improved double carriers in the manner hereinbefore described.

I make no claim either to the grooves, hinged sliding panels, cross wires, or buttons hereinbefore mentioned, save in combination with the other parts of my improved camera back and carrier, as similar devices have been employed for like purposes in the camera backs and carriers hitherto in use.

What I claim is:—1. Making a camera back with a single frame, substantially as hereinbefore described and shown. 2. Providing such frame with grooved guides, substantially as hereinbefore described and shown. 3. Making the carrier for photographic plates with a single frame and otherwise, as hereinbefore described and shown. 4. The improved construction of photographic camera back and carrier, substantially as hereinbefore described and shown. 5. The use in conjunction with such improved camera back and carrier of a light-tight bag furnished with an elastic nose or its equivalent for changing the carrier and plates, substantially in the manner hereinbefore described. 6. The application of my invention to existing camera backs, and to camera backs so made, by converting the two frames into a single frame and otherwise, substantially as hereinbefore described.

IMPROVEMENTS IN PHOTOGRAPH BURNISHERS.

No. 789. WARREN HIGLIMAN BOLES, Syracuse, county of Onondago, New York, U.S.—January 18, 1887.

This invention relates to machines for burnishing or polishing articles or materials of various kinds, but more especially photographs, and described with special reference to this class of machines my invention has for its object to economise the first cost of manufacture; gain time in heating the burnishing tool, and save cost and labour in heating; make a durable and easily adjusted machine, and one having readily removable parts, avoid collection of soot, and generally to remove objectionable features I meet with in such machines as have come under my notice in a long practical experience in the use and sale of this class of goods.

The invention consists in a tubular or flue burnishing tool, heated by a kerosene or other cheap burning fluid lamp, or by gas; means for adjusting and removing such tool; means for ascertaining, and thereby regulating its temperature; means for readily applying and removing the heater; and also a tubular ventilated feed roll.

The frame may consist of two upright castings, connected and braced by a table, detachably bolted thereto. The upper ends of these uprights are provided with housings for the journals of the feed roll, and this feed roll I make hollow so as to ventilate it and thus prevent condensation of vapours thereon, thus avoiding spoiling the picture or rusting the polishing tool.

The surface of this feed roll may be roughened or milled by means of a nurling tool in a lathe, to give it the necessary bite or friction upon the

picture to advance it regularly and uniformly over the burnishing tool. A hand crank may be attached to the feed roll to rotate it. The burnishing tool is located beneath the feed roll, and consists of a tubular casting, having the polished, and if desired, nickel-plated surface, the projecting arms at each end, which have tapped seats which rest upon pivot or fulcrum screws, arranged in screw-threaded lugs on the uprights.

These screws, by vertical adjustment in the lugs, admit of the raising or lowering of the burnishing tool with respect to the feed roll, and said screws may be set in such adjustment by the lock-nuts. The arms are connected by a rod to prevent their warping out of alignment with the screws.

On the opposite side of the burnishing tool a central arm projects out over the table, and is provided with a temper screw whereby the requisite pressure may be given to the picture, said screw bearing or seating on the table to this end, and its rotation in the arm serving to move the burnishing tool as a lever upon its pivot screws. This construction enables me to gain complete and instant control of the pressure upon the pictures.

Obviously by lowering the arm on its screw, the tool may be readily removed from the machine for repair, or cleaning, or replacement. Damage to and loss of pictures are of quite frequent occurrence in burnishers now commonly used, owing to the lack of provision for ascertaining and regulating the heat. In my invention the burnishing tool is made hollow and open from end to end, holes being made in the uprights in alignment with the tool so as to obtain a through and through passage. An opening is made in the lower part of the tool, about midway of its length, and this opening has at one side a stationary fender, and at the other a hinged fender or hood, and in this opening and between these fenders is received the chimney of an ordinary coal oil or other burning fluid lamp.

The hinged fender permits the ready insertion and removal of the lamp or heater. The burnishing tool being hollow and open from end to end a natural draught will be had through it, and combustion will be stimulated and the rapid heating of the tool ensured. A thermometer is applied to the burnisher in order to enable the operator to ascertain and regulate the temperature of the burnisher. The wick of the lamp will be raised and lowered to increase or diminish the volume of flame and heat according to the indications of the thermometer. Some of the advantages of my invention are as follows:—

1. There is never any possible danger of the picture being spoiled by the smoke coming in contact with the face of the same, as the smoke emerges within the flue, and is carried off at the ends of the same by the draught.

2. The accumulation of soot under the burnishing tool is avoided by the draught through the flue, which carries off all the smoke, and thus saves the necessity of using the fuel to heat the soot over and over again, as is the case with all burnishers having no draught.

3. The tension is even and invariable, absolutely positive and alike on both ends, and gained by leverage from one point, and hence there is no possibility of the picture running crooked or being twisted.

4. The heat can be graduated at command, by simply raising or lowering the wick of the lamp, and can be accurately gauged by the thermometer, consequently the chance of blistering or discolouring by getting the burnishing tool too hot is avoided.

5. My machine will burnish the cards equally as well on the edges as in the centre, as the heat is uniformly distributed by the draughts created by the flues under the burnishing tool drawing the heat uniformly from end to end of the tool.

6. The burnishing tool can be cooled much more rapidly than any other, as it is only a hollow tube of metal, instead of a solid block of iron; hence, if it is necessary to remove the burnishing tool to remove a scratch from the face of same, it can be readily done without danger of burning.

7. The thermometer attached to the side of the flue will tell precisely what degree of heat the burnishing tool has attained; consequently, one is not compelled to remain in doubt, and thus saves the necessity of defacing two or three pictures before ascertaining whether the burnishing tool is in proper condition for work.

8. There is no possibility of any moisture forming or condensing on the feed roll or polishing tool during the process of heating, because the feed roll is made hollow its whole length, thereby creating an air chamber through the centre of the same from end to end; this positively avoids the serious danger of spoiling the polishing tool or pictures by contact with such moisture.

Prior to my invention, it has been customary to roughen the surface of feed or pressure rollers by longitudinally serrating them by draw-filing, but this is an expensive operation.

I accomplish this roughening in a better and far more expeditious manner by the use of a nurling tool in a lathe.

The invention herein is applicable to mangles and calendering machines.

What I claim is:—1. In a burnisher, a tubular burnishing or polishing tool, open from end to end, and having an opening to receive the chimney of the heating lamp, and a hinged fender or hood to permit ingress and egress of the lamp combined with such lamp, substantially as described. 2. In a burnisher, a tubular burnishing or polishing tool, open from end to end, and having an opening to receive the chimney of the heating lamp, and a hinged fender or hood to permit ingress and egress of the lamp, and a stationary fender co-operating with the hinged fender to enclose the upper end or outlet of the lamp chimney combined with such lamp, substantially as described. 3. In a burnisher, a burnishing tool provided with fulcrum arms, and adjustable pivot or fulcrum screws on which said arms rest, and an intermediate temper screw, substantially as described. 4. In a burnisher, the burnishing or polishing tool, and a heater therefor, combined with a temperature-indicating device, such as a thermometer, substantially as described. 5. In a burnisher, the tubular feed roll, open from end to end to ventilate the same, combined with a burnishing tool and means to heat the latter, substantially as described. 6. The feed roll of a burnishing machine, the acting or feeding surface of which is nurlled, as distinguished from draw-filed, substantially as described.

The premises of Messrs. Batist & Son, photographers, 516, Oxford-street, London, have been destroyed by fire.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

LAST Tuesday night, at a meeting of the above Society, held at 5A, Pall Mall East, London, Mr. William England, Vice-President, occupied the chair.

The CHAIRMAN said that he had just received a note from Mr. J. Traill Taylor, stating, on behalf of a committee, that as Mr. W. K. Burton was about to leave this country, it is intended to give him a farewell dinner on Wednesday, March 30, at seven p.m., in the Holborn Restaurant; tickets 4s. 6d. each. Those intending to be present should give their names to either Mr. Taylor, 2, York-street, Covent Garden, London, or to Mr. T. Bolas, 5, Farnival-street, Holborn, London, in order that adequate arrangements might be made. All were invited to attend. He (the Chairman) thought that many of those then present and many others not present would be glad to give a farewell entertainment to Mr. Burton, who was a useful member of the Society and a genial companion; he hoped that a large number would be present to show their hearty appreciation of him.

Mr. J. TRAILL TAYLOR added that it was imperative that all who intended to be present at the dinner should let either Mr. Bolas or himself know by midday next Tuesday.

Mr. J. R. GOTZ exhibited an improved camera, as described recently in these pages.

Mr. R. L. KIDD exhibited two bromide prints upon opal glass, which he believed to be the first which had been publicly exhibited, and in that very room, in the year 1880; he believed that they were the first which had been produced commercially. They had been since much exposed to the sun, so that the exposed part of their plush backing, which he exhibited, had changed colour considerably, yet the adjacent whites of the opalotypes were as pure as ever. He also exhibited old and large bromide prints on paper, which he said had not altered in colour more than plain paper would have been likely to have done under the same conditions; one of the prints was a likeness of the late Sir G. B. Airy, Astronomer Royal.

Mr. W. BEDFORD asked if a warm tone could be given to the prints.

Mr. KIDD replied that it could by mercury treatment followed by ammonia, but then they possibly might be liable to fade. In finishing an enlargement much might be done to make it look less cold; his firm used pure Indian ink in the deep shadows and cooled it down with cobalt blue towards the lights.

Mr. BEDFORD exhibited a bromide print which he had exposed to direct daylight since October 18, 1886, with opaque letters placed upon it; the light had had some slight effect in printing in the letters, but not more, he said, than had plain paper been substituted for the bromide print.

Mr. H. J. BURTON exhibited a print taken by Mr. McMahon, of Aberdeen, about the beginning of 1886, and which since had so faded as to be worthless except where protected at the edges by the frame; he said that every care had been taken in its production.

Mr. INCE had had similar fading, and had traced it to imperfect washing out of the acetic acid used for clearing.

Mr. Herbert Fry exhibited bromide prints; some of them were *menu* cards copied from drawings; he also exhibited applications of the process to thick and rough drawing papers.

Mr. J. JACKSON, a representative of the Eastman Company, exhibited bromide prints, including some excellent ones printed in Paris from wet-plate negatives. He also exhibited some views of his own, taken in Cassiobury Park, near Watford, upon Eastman's stripping films, in relation to which films he promised to hereafter give a demonstration to the Society.

Mr. T. SEBASTIAN DAVIS thought that the films would be good for cloud negatives.

Dr. W. F. DONKIN called attention to *The Indian Journal of Photography* for January, 1887, edited by Professor Sheppard, of 64, Dhurrantollah-street, Calcutta, in which Mr. C. R. Newton had written about prints upon the Eastman paper. He squeezed them down upon oiled glass, and varnished them with gold size dissolved in benzole, after which they were not injured in the printing. He (Dr. Donkin) thought that in time stripping films would abolish paper for negatives.

The CHAIRMAN thought that the gold size would not give sufficient protection in printing long numbers. The objection to stripped films was that they could not be varnished.

Mr. KIDD had found horny collodion to protect gelatine negatives better than did varnish.

The CHAIRMAN had not found it so.

Mr. A. SPILLER thought that much depended upon the kind of collodion used.

Dr. DONKIN had found Obernetter's paper to compare favourably with albumenised paper in the results.

Mr. W. E. DEBENHAM stated that some persons complained of the coldness of bromide prints who also spoke of the delicacy of platinum prints, so they seemed to be a little inconsistent.

Mr. F. T. BEESON said that in enlarging upon bromide paper it was difficult to get a good picture unless the right time of exposure had been hit upon. Could any one tell how to avoid this by modifying the development?

Mr. SPILLER replied that a good print could not be obtained if the operator were clumsy over exposure. A good print could be obtained upon bromide

paper from an indifferent negative. Such was not the case with platinum paper.

Mr. C. F. FRITCHARD said that a platinum print had more detail in the shadows. Mr. DEBENHAM thought that that was just where platinum prints were found wanting; pictures dense in the high lights were specially suited to platinum printing.

The CHAIRMAN remarked that it is difficult to get good bromide prints from a hard negative. He then exhibited two prints from the same negative, one upon bromide and the other upon platintype paper; the latter was the best.

Mr. DAVIS said that one or two isolated examples proved nothing. Mr. Keene's negatives were taken specially for the platintype process.

Mr. FRIESE GREENE had found bromide prints to be permanent during the five or six years he had been turning them out; he found that the public appreciated them, and the bromide prints had improved his trade wonderfully.

Mr. KIDD said that his experience was that cultured people liked the black tones better than the ordinary photographic colours.

Mr. W. R. ROBINSON asked if anyone present had had experience in toning bromide prints with platinum.

Mr. BOLAS said that those who intend to come to Mr. Burton's dinner can pay when they are present at it, but the Committee want to know by Tuesday next how many are coming.

The meeting then broke up.

THE LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

ON Thursday night, March 17, at the ordinary weekly meeting of the above Association, held at the Masons Hall Tavern, City, London, Mr. W. H. Prestwich presided.

Mr. H. M. HASTINGS said that he had made a very rough analysis of "anti-calcaire," and it seemed to be "soda-lime;" it contained some carbonate, for it effervesced with acids.

Mr. A. L. HENDERSON remarked that it was a reducer, for he had developed photographs with it.

Mr. J. B. B. WELLINGTON exhibited platintype prints of snow scenes; the negatives were taken upon Hampstead Heath during the fall of snow, with five seconds' exposure.

Mr. L. Medland also exhibited prints of snow scenes.

Mr. J. J. BRIGNSHAW exhibited prints upon platintype paper which had been kept for two years before exposure; the paper had been kept in its chloride of calcium tube in a permanently warm and dry cupboard all the time; the temperature of the cupboard was about 70° Fahr. The prints were flat and dim.

The CHAIRMAN remarked that Mr. Willis himself only estimated the life of platintype paper at two months.

Mr. H. A. BRIDGE had found it to become useless in about six or seven months; his samples usually kept good for about that time in the chloride of calcium tube.

Mr. A. MACKIE said that ready-sensitised silver paper usually improved a little at first by keeping.

A question in the box asked: "A customer demands that the negatives of some portraits that were taken and paid for in the usual way some time since should now be given up to him without further payment; can he have any legal claim to them?"

Mr. BRIDGE said that he had no claim whatever; the photographer contracted to deliver, say, a dozen *cartes*; it was nothing to the purchaser how the photographer produced them; he might have turned them out with a coffee mill if he liked.

Mr. HENDERSON asked if an action would lie against a person for selling a photograph for a Christmas card without the consent of the sitter.

Mr. A. COWAN thought that it would.

Mr. HENDERSON added that at all events it would be a breach of trust on the part of the photographer.

Mr. J. R. GOTZ found that orthochromatic plates produced by bathing had their rapidity thereby increased; with such plates a yellow screen must generally be used in daylight, or in any light very rich in blue rays. Obernetter had produced some plates which could be used in daylight without a screen, and could be kept without alteration for at least six months; he had not yet received any of them.

Mr. J. TRAILL TAYLOR said that, to the loss of the Association and of British photographers, although to his own gain, Mr. W. K. Burton was about to leave England for Japan, as Professor of Sanitary Engineering in the Imperial Institute of that country. It was a good government appointment. He would sail on that auspicious day, the first of April. Seeing that Mr. or, as he would now designate him, Professor Burton had long been a valued member of their Association, he (Mr. Taylor) felt that he was only doing right to make this announcement, in order to afford them an opportunity of expressing their sentiments on such an occasion.

The Chairman stated that the Association would greatly feel his loss.

Mr. W. M. ASHMAN, as Vice-Chairman, said that all the other photographic societies would also miss him.

Professor W. K. BURTON responded that the remarks which had been made were exceedingly kind, and he must say very seriously, that although all his friends said that it was a good appointment, he felt thoroughly miserable and wretched about going away, chiefly because he had to leave all the friends he had made in photographic circles. The greatest pleasure he had had since he came to London years ago had been in meeting congenial spirits in photographic societies, and he had attended more of the meetings of that particular Association than he had of any other. He regretted to have to leave them for a few years, and when away he should often think of their kindness to him.

Mr. HENDERSON proposed, and Mr. COWAN seconded, that Professor Burton should be elected an honorary member of the Association during the term of his absence.

This was carried with acclamation.

Mr. COOK thought that the Association should possess the portrait of Mr. Burton.

Mr. TAYLOR thought so too, and would undertake to present one to each member. He stated that in consequence of the interest which had been exhibited by photographers at a recent public sale in a book by Bigelow he had brought it to exhibit to the members that evening. The work was *Artistic Photography, and How to Attain it*, by L. G. Bigelow. He then suggested a discussion on the question why cyanide of potassium was not more used for fixing gelatine plates.

Mr. HENDERSON mixed a little of it with his thiosulphate of soda solution when the latter fixed pictures slowly.

The CHAIRMAN had used it extensively for fixing gelatine negatives.

Mr. ASHMAN said that bromide of silver would fix more rapidly in thio-sulphate of soda than in cyanide of potassium, but that if the emulsion contained iodide the conditions might be altered.

The HON. SECRETARY asked for a formula for preparing a fine-division plate which would do for photo-microscopic purposes.

Mr. HENDERSON thought that bromide of zinc might do to make an emulsion for the purpose; it threw down bromide of silver in so fine a form that it might be washed out of the emulsion; it ought to be a slow plate for the purpose mentioned.

Mr. MACKIE asked if glycerine had any solvent action upon chrome-almud gelatine.

Professor BURTON remarked that a statement had been made that in the case of a stripping film attached to paper by soluble gelatine it was said that when the latter became insoluble the film could be got off by adding a little glycerine to the warm washing water. It seemed to be highly improbable, and he should like to know if it were true. Acids or alkalis would help to get off the film after some of its chrome alum had dialysed into the soluble substratum; he usually added a little citric or acetic acid to the warm water.

Mr. COLES thought that much depended upon the gelatine whether the film would or would not come readily off a glass plate.

Mr. MACKIE said that Mr. S. G. B. Wollaston had made the statement about glycerine.

Mr. ASHMAN suggested that Mr. Wollaston should be invited to demonstrate the matter experimentally before the Association.

This was agreed to, and the meeting broke up.

CAMERA CLUB.

On Thursday, March 17, Mr. H. J. GIFFORD gave a demonstration and explanation of his method of making collodio-bromide emulsion and coating of lantern plates therewith. Mr. H. H. O'Farrell occupied the chair.

Previous to the address the CHAIRMAN drew attention to the projected excursion of members and friends, arranged for April 16, to the Hayes and West Wickham district, and

Mr. DAVISON made some remarks upon an interesting set of prints which were mounted upon one of the Club screens. These were prints from negatives of fireworks and illuminations at a Calcutta Jubilee celebration, taken by Major Waterhouse upon plates that he had treated orthochromatically, and were specially interesting coming from such a source.

Mr. GIFFORD went through his demonstration, and explained upon the black-board how he arrived at his formula. An adjournment was then made to the dark room, and some plates were coated and others previously prepared exposed and developed.

In the discussion which followed, Mr. J. KING said that to obtain clear glass he had at times thought that a somewhat rapid development should be given. If kept long under development or with any forcing the plate was clouded. This, he thought, was staining. He had noticed that some gave clear glass, others from the same batch, under exactly the same treatment, showed stains, and if proceeded with further gave dichroic fog.

In answer to a question whether paper could be coated with collodio-bromide emulsion, Messrs. GIFFORD and KING gave affirmative replies.

The discussion was continued by Messrs. ATKINSON, DAVISON, and GALE, and in conclusion the CHAIRMAN remarked upon the interest this subject should have. It was hardly to be expected that collodion plates were coming in again, but still it was said that Mr. J. B. B. Wellington had lately made some very rapid orthochromatic collodio-bromide plates, and it was possible that we might return to the old collodion film, which certainly had some advantages over gelatino-bromide.

On Thursday, March 31, an exceptionally interesting lantern slide exhibition has been arranged. Slides will be shown or sent by Messrs. F. Dunsterville, C. B. Wright, Frith, and Gale. Dr. Johnson will exhibit some microscopical slides with a new arrangement, and Mr. Frank Howard will exhibit slides and make some remarks specially in regard to printing-in of clouds. The exhibition will commence at eight p.m.

MANCHESTER PHOTOGRAPHIC SOCIETY.

LANTERN SECTION.

The usual monthly meeting of this Section was held at 36, George-street, on February 23, 1887,—Mr. John Schofield in the chair.

The HON. SECRETARY of the Lantern Section, Mr. W. Watts, said he expected a number of exhibits for the evening, but was disappointed, as many had not turned up. He was pleased to say some beautiful slides had been received from Mr. George Smith (the Scioptic Company) and a large parcel of well-executed coloured slides from Messrs. Wilkinson, of Sunderland.

The CHAIRMAN said the first business was a discussion upon the comparative results of gas in high-pressure bottles and gas in bags, if the members had had an opportunity of judging from the use of both at the last meeting of the Section. Personally he was not at all satisfied with the performance of gas bottles as used at the last meeting. The light from them was certainly very intense, and probably necessary when you had large discs and great length of room to contend with, but which you did not meet with in ordinary lantern work, but in a moderate room he believed them to be useless. It was, he

thought, quite possible to have too much light, for beyond a certain power it was wasted. He found that if in ordinary daylight we could get a disc of ten feet with a "blow-through" jet thirty feet off which was just visible, that was sufficient for most purposes, and if you got a light more intense than that you would get something that was not natural and which would expose the defects of the slides; on the other hand, gas bags would give all that was required from forty to sixty feet with mixed jets. The objection to bags was that they were too bulky, but they were, in his opinion, the best arrangement we have at present.

Mr. W. L. CHADWICK said the question was, Were the bottles a success at the last meeting? He thought not. He said whether we use gas from bottles or bags, if it came out at the same pressure the light would be the same. Higher pressures with suitable limes and jets gave a more powerful light, and he admitted the light was at the last meeting brighter when the bottles were used than when the bags were substituted, but the bags had not fair play. When Mr. Jones (who worked the lanterns) started he had ninety atmospheres of pressure in the bottles, and the reducing valves were set to allow the gas to issue at a high working pressure, and the gas, which cost 25s., and 5s. carriage to Manchester (being at the rate of 8d. per foot for oxygen, and 6d. for hydrogen), was used in an hour and a quarter; this, he said, was used sooner than it otherwise would have been by reason of Mr. Jones having both lanterns lighted up at one time and dissolving by an arrangement in front of the objectives; but why did he not use the dissolving tap? Mr. Jones said, in reply to this question, that the high pressure was "too great a strain on the dissolving tap." Now, turning to the bags, Mr. Jones had only three fifty-six-pound weights on his double pressure boards, using the largest size bags, and this he thought was not enough for a sixteen-foot picture, or, at all events, to show in comparison with bottles working at a much higher pressure; personally, he frequently used as many as five fifty-six-pound weights on his own bags, which had been in use five or six years. Then, again, everybody knows the hard limes are not so suitable for low pressures, and in Mr. Jones's case he had *special hard limes* for the bottles, but he likewise used these *extra hard limes* when the bags were being used; that, again, was unfair to the bags. Under these circumstances, he said, the so-called test was no test at all. He was quite in favour of any arrangement which would be more portable and convenient than gas bags, and gave a description of some of the methods he had seen in use in America, and thought for amateurs the arrangement of Mr. George Pronse, of Montreal, was very good, namely, filling a cylinder of about three feet cubic capacity by means of water pressure, which was in Manchester from sixty to seventy pounds in many places. He also described an arrangement used by many Americans, where the retort was also a holder, and the gas generated in a strong retort of about a cubic foot capacity to a given pressure; he had seen a most successful exhibition conducted by this arrangement, namely, using the gas straight from this retort and holder combined.

Mr. J. G. JONES said the reason why he did not dissolve at the back was that Mr. Chadwick sent him a message from the platform to the effect that he should like the slides to be got through quicker, as there were a great many to show, and he (Mr. Jones) simply left the two lights on to facilitate matters. He started with twenty-one feet of oxygen and nineteen of hydrogen, all of which he should not have used had he had time to arrange his lights. Why he had gone in for bottles, was size of disc, distance, and portability. With the bottles you got greater pressure than with the bags. He considered it unsafe to use more than three fifty-sixes on bags, as you never knew the state of bags. Five fifty-sixes was an excess of pressure for any size bags.

Several members said they frequently used as many as five. Mr. LEADER WILLIAMS said he agreed with Mr. Chadwick that five fifty-sixes might be used with comparative safety on large bags, but, on the other hand, was bound to say he had never seen anything extra in the light when more than three were used; and, in reply to Mr. Chadwick, said he referred to blow-through jets taking the hydrogen from the main.

Mr. CHADWICK said that he thought five fifty-six-pound weights were sufficient for general use; then why did we go in for these excessive pressures? Simply for portability sake, and that was more than balanced by the extra cost. Referring to the respective cost of gas in bottles and bags, he said at the present time eight feet of oxygen at 8d. per foot would be 5s. 4d., ten feet of hydrogen at 6d. would be 5s., with 5s. carriage to Manchester, made a total of 15s. 4d., against which we could produce the same quantity at home for 2s. As far as economy was concerned, both with respect to the gas and the plant, and the maintenance of it, the bags had the advantage considerably.

Mr. MELLOR had had some years' experience both in the use of cylinders and bags. Supposing the bags were suitably weighted, he could distinguish no difference on the screen. The only fear he had about using oxygen was that you were unable to see what was the state of the inside of the cylinder. The only advantage bottles had over bags was portability. He thought the question to be discussed was how many inches' displacement of water is the proper pressure for certain sizes of discs.

The CHAIRMAN thought about six inches' water pressure for the ordinary exhibition room, but if you want to use blow-through jets four inches of water pressure was plenty.

Mr. CHADWICK said bags and pressure boards were not a very good mechanical contrivance, the pressure was ever varying according to the position of the pressure board on the bags. He had received a letter from a member asking him to state whether pumice stone, gauze, &c., were necessary in the mixing chamber, to which he might say that he never used anything of the sort.

Mr. FURNIVAL contended that if you wanted extra pressure for long distances you could get it with more safety from the bottles than the bags.

Mr. WILLIAMS advised amateurs who wished to show their pictures to advantage not to use above an eight-foot disc. A large disc weakened the picture, while a medium-sized one made it richer and fuller.

Referring to the durability of gas bags, Mr. CHADWICK said his present bags, which were in good order, had been in continual use every season for five or six years.

Mr. OKEL said he had used his bags many times every year, and he had only had two bags in twenty years.

Several other members spoke to the same effect.

Mr. Chadwick then proceeded to show some slides sent by Mr. Smith, of the Scioptic Company (*Hedgerow Studies*), using a single lantern and Beard's new "self-centering eclipse carrier." The effect was very good, and most members were delighted with the effect. Phillips's carrier was also shown.

The ordinary meeting of this Society was held on March 10, 1887, at 36, George-street.—The President, Mr. A. Coventry, in the chair.

The minutes of the previous meeting were read and passed, and the ballot taken for Messrs. Robert Peel and W. Tomlinson, both being elected members.

The entire evening was occupied in inspecting a collection of members' pictures and selecting a presentation print to be given to each member of the Society whose subscription was not in arrears. The exhibition was not a very large one, and many members did not compete for the presentation picture. Eighty-two pictures were, however, submitted to the judgment of the members, the selection being by ballot, and finally Mr. Chadwick's *View of Conway* was declared the winner.

NORTH LONDON PHOTOGRAPHIC SOCIETY.

At the meeting held at Myddelton Hall, Islington, N., on Tuesday, March 15, —Mr. J. Traill Taylor, President, in the chair,

Mr. F. W. Hart, a member of the former North London Society, was elected an honorary member.

A question from the box was read, asking whether a mixture sold as fifteen grains of chloride of gold and sodium, seven and a half grains being pure chloride of gold, was the same preparation as that usually labelled fifteen grains of chloride of gold, seven and a half grains being pure metal.

Mr. F. W. Hart said that such tubes should contain seven and a half grains of metallic gold, but that sometimes fifteen grains of the mixed chlorides contained eight or eight and a half grains, while if weighed in a moist atmosphere enough water would be absorbed to reduce the amount of metal to seven grains.

Mr. L. MEDLAND asked the experience of members in photographing snow scenes.

The CHAIRMAN said that to get the best effects a full exposure was necessary; a small stop should be used and the exposure prolonged so that detail in the shadows was fully developed before the snow-covered portions became too dense.

The CHAIRMAN then called upon Mr. E. Clifton to read his paper on *Cameras, Ancient and Modern* [this will appear in a future number].

The paper, which was illustrated by blackboard diagrams, having been read,

The CHAIRMAN said that among the cameras of a former period there was one of which no notice had been taken in the very comprehensive paper just read; he referred to the panoramic camera of Sutton, and which was of a typical character. As some of them doubtless were aware, the picture was received on a long cylindrical plate, every portion of which was in focus. He then described by what means he (the speaker) adapted the camera for using a long strip of sensitised paper, which, being pressed against the cylindrical glass, was kept in proper shape. To the dark slide he had adapted a roller at each end on which to wind and unwind the paper. He had also employed with it an ordinary lens instead of the spherical lens of Sutton. Concerning double dark slides, he spoke approvingly of a system much employed in America, although of English inception; this slide permitted two plates to be inserted in a groove at the end, the plates then being kept in position by a wooden or other opaque slide going between them, and by which all light was debarred access to the plates. Other desirable features in American cameras and slides were alluded to, more especially the manner in which the wooden square carrying the lens was stepped into a recess in the camera front instead of being slid on, and the complete withdrawal of the shutter from the dark slide while making an exposure. He endorsed all that had been said about Mr. McKellen, of Manchester, of one of whose latest productions—a 10×8—he was proud to be the owner, as in it was embodied all those features he considered necessary or desirable in a camera, especially for outdoor work. He could not conclude without a word of recognition of the ingenuity of Mr. C. G. H. Kinneir, of Edinburgh, who was the originator of the type of camera with the conical bellows and sliding baseboard.

Mr. MEDLAND said that he had been using Shew's adapter with his camera, and had found it very useful.

Mr. F. W. Cox asked if there was any advantage in having a side swing fitted to the front as well as the back of a camera.

Mr. CLIFTON thought not; in fact the side swing was seldom required at all, and called for much judgment on the part of the operator when it was used.

Mr. HART said that Mr. Clifton had described an universal plate holder for the dark slide. He had many years ago made such a contrivance to take plates from 30×24 downwards of any shape or size. Mr. Clifton had mentioned Mr. Harrison's name in connection with his little metal camera, but had not touched on his share in perfecting the pantoscopic camera patented by Mr. Johnson.

Mr. Fuller exhibited an Ashford's camera stand capable of supporting a 12×10 camera.

Mr. HART exhibited and fully explained a very perfect whole-plate camera with a jointed baseboard giving a range of focus from three to forty-four inches; only so much of the baseboard as was in use need be attached to the body. It could be used for copying general studio and landscape work, and possessed every possible adjustment.

A vote of thanks to Mr. Clifton was carried by acclamation.

The next meeting will be a technical one and will be held on Tuesday, April 5.

NORTH SURREY PHOTOGRAPHIC SOCIETY.

On Wednesday evening, March 16, this Society held its fortnightly meeting at the Greyhound Hotel, Dulwich.—Mr. Bromley Smith occupying the chair.

Mr. RYDER read a communication on *Bromide Paper*, previous to which some very fine prints on the Eastman paper by M. Nadar, of Paris, were exhibited, and were greatly admired. Mr. Ryder described M. Nadar's formula

used in the production of these prints. Mr. Ryder advocated the following modification of the formula published for use with the Eastman paper, namely, the oxalate to be increased to nine parts to each part of iron, and the bromide to be reduced to half the quantity stated.

Mr. H. SENIER (Hon. Secretary) gave a description of a series of experiments he had recently made with a view to obtaining a variety of tones in bromide prints and enlargements. Mr. Senier first converts the silver of a bromide picture into chloride by bleaching in chlorine water, after which he redevelops with ferrous oxalate or pyro; a variety of shades of red and brown can be then easily obtained by the use of bromide of potassium in the developer in greatly increased quantities, as much as twenty grains per ounce being used for warm red tones. A notable fact in connection with this process is that the redevelopment must be conducted in actinic light, otherwise no redevelopment is possible. Bromide prints which have been spoiled by over exposure can be made into good prints by this method, as the redevelopment can be stopped at any stage, a fact which is important when working large sheets of paper. Another method for producing pleasing tones in bromide prints was suggested by Mr. Senier. The print is immersed in chlorine water and partially bleached until a thin layer of chloride of silver is formed; this is easily recognised by a milky appearance being seen on the surface of the picture. The print is then washed and exposed in a strong light until the chloride of silver is reduced to a warm tint. Specimen prints illustrating each of these experiments were exhibited.

Mr. Wolff submitted for inspection some chronographs for timing photographic exposures. They are the manufacture of Messrs. Lizard & Son, and will be much appreciated by photographers.

The next meeting will be held on Wednesday, March 30, when Mr. J. Thomson, author of *China and its People*, has kindly consented to deliver a lecture on *Travels in China with the Camera*.

Correspondence.

THE RIGHT TO THE NEGATIVE.

To the EDITORS.

GENTLEMEN,—A point of great importance to photographers has just been raised by a customer whose wife's portrait I took ten years ago. The lady has recently died, and her husband now demands that I should give up the negatives to him without any payment. He demands this in the most imperious manner, saying that I am withholding his property, to which I have no legal claim whatever. Of course I refuse to do so. At the time they were taken twelve cabinets were supplied, for which 25s. was paid in the usual manner, without a word passing in allusion to the negatives.

As it is usually taken for granted that a photographer's negatives form an important item in his assets, this is a question of serious importance to the whole profession, and I write to ask your advice on the subject. The claim appears to me to be wholly unjust, and indeed preposterous. As the gentleman threatens to take prompt proceedings in a court of law to secure their delivery and enforce his point, it would be interesting to hear a high authority on the subject before entering upon the defence.—I am, yours, &c.,

ARTHUR DEBENHAM.

Royal Photographic Studio, 28, Union-street, Ryde, I.W., March 21, 1887.

ORTHOCHROMATIC PHOTOGRAPHY.

To the EDITORS.

GENTLEMEN,—In reply to a suggestion made by one of your correspondents a few weeks back I am now enabled to state that Dr. Vogel's azaline will very shortly be a commercial article in this country.

It will, it is intended, be sold in small bottles as tincture, and will no doubt be found a useful addition in the photographic dark room, for plates stained with it will keep from two to three months.—I am, yours, &c.,

J. R. GORTZ.

19, Buckingham-street, Strand, W.C., March 23, 1887.

STRIPPING FILMS.

To the EDITORS.

GENTLEMEN,—Owing to the very short time the Eastman stripping films have been before the general public there remains considerable uncertainty about them, and therefore the results of twelve months' experience may be of some value to those who are considering the advisability of taking to roll holder and films.

One of the supposed drawbacks to the films was the fear that in course of time the insoluble coating would affect the soluble substratum and prevent stripping, and this fear on the part of the makers delayed the issue of the films for nearly twelve months.

Exactly twelve months ago I received five spools of strippers (10×8), and the ease of carriage caused them to be subjected to many hundred miles' travel, for wherever I went they went in the hope of something photographic turning up.

Last August found me in Devonshire, and there I exposed the last of my five spools; on developing there were one or two negatives which I thought not worth keeping, and they were about to be consigned to my waste basket when the thought struck me that I might keep them for six months and then try to strip them to test the truth of the statement that films would not strip after being developed and dried, and I have

now the great satisfaction of saying that on Saturday last, six months after development and drying, I stripped them without the least difficulty, the paper backing coming off as freely as those freshly developed.

This I think is most important information for the tourist photographer who may from time to time desire to test his exposures, and yet afraid to do so lest he lose a good picture through not stripping at once. He can now with all confidence develop when he likes, and strip when he comes home.—I am, yours, &c.,

WM. H. HYSLOP.

City Liberal Club, Walsbrook, E.C., March 23, 1887.

DOUBLE PRINTING AND RETOUCHING.

To the Editors.

GENTLEMEN,—I notice in the issue of last week's JOURNAL, the 18th, that two of my friends, Mr. Dunmore and Mr. Pringle, have made kindly remarks regarding the subject which I took up at the Photographic Club and also the Camera Club lately. My remarks then, regarding double printing and also retouching, were merely by the way. Of course I anticipated they might probably provoke discussion, as my views on these points are very decided. I am very sorry to appear to be clipping the wings of any department taken up by a few clever men connected with the photographic profession, who have shown considerable knowledge and feeling in the treatment of a subject.

I still hold the value and importance of a pure photographic production derived from without, as that which claims the very highest respect as a work of art because it is unaided. I admit that there may be as much knowledge required for building up a composite negative, and there may be as much necessarily of the individuality of the composer's mind in so doing it as there is in taking it directly from an arranged tableau or a carefully chosen spot of a landscape; but from what I have seen yet of built-up composite pictures they are never to be compared to the naturalness of work well under management, composed from actors capable of entering with all their soul into the feeling of the subject.

In my address I sought to define the province of photography, and assigned as a reason for the resemblance of photography to dramatic art, just in this respect, that the best method for producing pictorial effects were synonymous with stage arrangements for dramatic expression.

However, this is only my opinion, and I shall abide by it till I see something equal to the desirable results which I strongly advocate and recommend in its pursuit.

There is much in favour of what both Mr. Dunmore and Mr. Pringle maintains in regard to double printing for skies, but I still—if at all possible—like to see the difficulties in photography struggled with, and not yielding to easier methods when direct or simultaneous negatives composed of land and sky cannot be conveniently taken.

For the same reason I advocate doing away with that unworthy method of stippling or hatching on the surface of a face (for it is not art) often consigned to a few girls, who very few of them can draw a bit; all that is valuable in character and history swept away for the sake of some fancied superiority of a style long effete in painting. In the JOURNAL of March 11 there is an article entitled *Methods of Retouching*, in which the writer strongly recommending "a bold and dashing effect, a very taking picture will result." He says, "Notwithstanding all that can be said in favour of this method, it always will have its glaring disadvantages as regards portraiture generally. For what is termed publication pictures it is undoubtedly good, as a brilliant result is certain to be obtained, and the loss of likeness is scarcely a disadvantage. In pictures of this class the resemblance is a matter of very secondary consideration. The public will not buy an *ugly* portrait, especially when it is of some one they do not personally know; but they will buy a 'pretty picture,' and make themselves believe it is also a correct likeness. Whether the public be right or wrong in this regard I will not dare to offer an opinion," says the writer. "I will only say with the old showman, 'They pays their money and they has their choice.'" Such is an extract on this subject, which clearly shows how secondary a consideration is the matter of truth and conscientious working when it won't take and bring in the £ s. d. This lies at the foundation of unhappily too much of the procedure in photographic art called retouching.

Mr. Pringle, while speaking on retouching, asks what good reason can be stated why we should be bound to leave portrait negatives with all their facial colour defects not only reproduced but exaggerated. I stated in my address that authenticity was a much valued quality or attribute in photography, and if lines or freckles unduly presented themselves it was only the result of under exposure; by giving plenty of exposure these are no more visible in the negative than they are in the subject, perhaps not so much. It is the presence of these that renders the face very human and very realistic. These are my arguments which I submitted in favour of the proposition of doing away with retouching.

Mr. Pringle may keep himself quite easy about disturbing "the sacred precincts of painting." It won't be either combination printing or retouching that will revolutionise fine art. Mr. Pringle exempts all such work as he has been advocating from exhibitions, and says, "A photographic exhibition should be an exhibition of photographs, not of drawings, nor etchings, nor paintings." Is this not an acknowledgment that he considers all such labour on a negative as alien to pure photography?

NORMAN MACBETH, R.S.A.

P.S.—I beg to say that this is the last observations which I shall make on this part of my late lecture.

EXHIBITORS AND EXHIBITIONS.

To the Editors.

GENTLEMEN,—Mr. H. P. Robinson in your last issue says that the publication of the discussion on his paper before the paper itself is printed, gives me an opportunity of ingeniously suggesting that he endeavoured to insult a foreign exhibitor.

Mr. Robinson's suggestion that I have taken some unfair advantage is entirely unjustifiable. It is not the delay in the printing of his paper, nor is it the earlier publication of your summary of the paper and report of the discussion, that "gives me the opportunity for suggesting" that Mr. Robinson had endeavoured to insult a foreign exhibitor. Mr. Robinson stigmatised the framing of this exhibitor's work as "vulgar." The work itself was so good that it earned a well-deserved medal, and I submit now, as I did on the reading of the paper, that an artist who produced such fine work should be credited with some taste, and that if his taste in the matter of framing is not in accordance with our own, it is in decidedly bad taste to call it vulgar. It is an old observation of mine that a too great readiness to apply the word vulgar, is, in itself, a very offensive vulgarity.

The opportunity for making a suggestion or comment upon a paper is afforded by the reading of the paper, and the invitation of the President for members to discuss it. The publication of the discussion before the paper is printed, does, however, afford Mr. Robinson an opportunity for bringing forward in your columns a discussion, whilst he has the advantage of being able to refer to the paper itself, and the other side can only trust to memory. I believe that my remembrance of the paper is pretty accurate, but in case I should make a slip in some minor detail this must be my excuse.

Mr. Robinson credits me with "ingeniously" suggesting that he endeavoured to insult a foreign exhibitor. Now, as he called that exhibitor's framing vulgar, and in his letter repeats that it was so vulgar as to damage the general effect of the exhibition, it seems to me to require no ingenuity, but a simple statement of fact, to say that such opprobrium is an insult.

Mr. Robinson further says that he welcomes the work of foreign exhibitors, for they receive his "with great cordiality." It is no doubt gratifying to be able to announce the cordiality with which one's work is received abroad as well as at home, but if this is a reason why Mr. Robinson should not insult a foreign exhibitor, it cannot be accepted as a reason that he did not if the fact remains that he did.

Mr. Robinson next assumes that "everybody of taste except Mr. Debenham" agrees with him that the mounts in question were vulgar. I have not yet expressed any opinion on the subject, but a gentleman, a writer very well known and respected in photographic circles, whose business it has been to criticise many exhibitions, gave me his opinion that "unique" and not "vulgar" was the proper term.

There were several other points in Mr. Robinson's paper from which I dissent, but I think the one which requires the strongest protest is his suggestion that the judges, or hanging committee, should show partiality, and favour the work of old exhibitors and those already well known. I do not say that those who have already received medals should be considered as out of competition, but surely of the two propositions the latter would have been the more graceful from the recipient of so many honours as Mr. Robinson has been.—I am, yours, &c.,

W. E. DEBENHAM.

A NEW LANTERN SLIDE CARRIER.

To the Editors.

GENTLEMEN,—I have just noticed an article with the above heading in one of the photographic annuals, and should like to bear testimony to the excellence of slide carriers made on the plan advocated by Mr. Hepworth therein. The idea, however, can scarcely be called *new*. On the 7th of February, 1884, at a meeting of the late South London Photographic Society held at the Society of Arts, I read a paper on *Willesden Paper and its Uses*, and among other suggestions I recommended it as a good material from which, in conjunction with thin wood, excellent light lantern slide carriers could be made, handing round two I had made that afternoon, one *exactly* as described by Mr. Hepworth in his article, and another in which a piece of the wood at one end could be slipped out from between the "paper" to allow the slides to be changed as often as might be required. I may add that I have a number (with this improvement) in my possession at the present time, which were made by my friend, Mr. Brooks, soon after my paper was read; and although they have travelled with us some hundreds of miles on our lecture tours, they are as good now as when first made.—I am, yours, &c.,

F. A. BRIDGE.

East Lodge, Dalston-lane, March 21, 1887.

A WANT IN THE COLONIES.

To the Editors.

GENTLEMEN,—Can you inform me if any of the numerous photographic dealers will supply a good gelatine emulsion that would stand exportation, say three months' keeping? Possibly a *very sensitive* emulsion would not keep, but a good, useful article might surely be manufactured fit for exportation. Amateurs and professionals at home, with dry-plate makers in every town, and prices varying from 4s. to 12s. per dozen for whole-plates, may not care to take the trouble to make their own plates,

but when the cost and risk of transit is considered, and the fact that almost every photographer out in the Colonies has dozens of spoiled negatives, the glasses of which are at present useless, is also remembered, you will not be surprised that some of us would like to make our own plates, if we could get a little help in getting emulsion ready made. At all events I throw out the hint for some enterprising manufacturer to take up.—I am, yours, &c.,
A. L.

Napier, New Zealand, January 26, 1887.

P.S.—Your JOURNAL and ALMANAC are invaluable. If you were six thousand miles nearer, you would have plenty of correspondence from the Antipodeans, who are doing well with the camera. Your numerous societies, where you benefit by each other's experience and see their experiments, must be grand helps! Here if anything goes wrong, it is a case of worry until it goes right, and the photographic stores do not always treat us well. Discoloured pyro, spotty paper, &c., play the very devil with our work!

PHOTOGRAPHIC ART IN CANADA.

To the Editors.

GENTLEMEN,—I think you will be pleased to hear that art photographs are now becoming most popular on this side of the Atlantic, to the exclusion of those foreign chromo and other meretricious daubs which have for so long a time disgraced our picture windows and middle-class homes. We have one Company alone who has issued a catalogue of 210 pages of matter, exhibiting for sale upwards of 100,000 art copies. This catalogue is divided into three parts:—1. Reproductions of original paintings, frescoes, and designs by the Old Masters; 2. Sculpture, architectural subjects, and miscellaneous views; 3. Reproductions of engravings, drawings, etchings, and modern paintings. Thus, at least, 10,000 original subjects are before us. In Canada, owing to the cheapness and choice of fancy woods and the plentitude of water-turning power, picture frames are produced very much cheaper than in any other part of the globe; and I quite expect to see art photographs superseding every other ornamental attraction in the tasteful decoration of our homes. If I can give you or your readers any other information I shall be happy to do so.—I am, yours, &c.,
ALEX. S. MACRAE.

127, Wellington-street, Toronto, Canada, March 2, 1887.

Answers to Correspondents.

PHOTOGRAPHS REGISTERED:—

John Owen, Newtown, North Wales.—Portrait of lady with lions.

W. EMPHALL.—Try Piper & Carter.

M.—We have not yet completed trials of the bath.

JAMES GRAY.—We feel interested in your experiments.

G. H.—Lacquer can be obtained from any dealer in varnishes.

W. D.—The address of Messrs. Frith & Son is Reigate, Surrey.

LUMINOUS.—Varnish will not impair the efficiency of luminous paint.

L. H. M.—So far as we can learn, there are no official photographers employed in dockyards or prisons.

RICHARD BLAKE.—J. R. Gotz, 19, Buckingham-street, W.C., is the agent for that special make of ferro-prussiate paper.

JAS. EDWARDS.—We have not yet had an opportunity of submitting your communication to the author of the article in question, but will endeavour to do so.

S. GRAVES.—The design for a studio as shown on sketch No. 2 will be the best for general purposes. No. 1 is better adapted for copying pictures than for portraiture.

F.D.—We are afraid that India, while interesting, would prove rather impracticable as a country to include in a *Where to Go with the Camera* series. Thanks, however.

G. PATTERSON.—It is clearly a case of dishonesty and sharp practice. With regard to the question of combustibles, the police have power to act under the Explosives Act.

FOG.—We attribute your failure to the intensely horny character of the film. The addition of a trace of glycerine, or even Scotch ale, to the emulsion will doubtless remedy the evil.

E. D.—1. We do not know.—2. Twelve dozen plates will suffice.—3. For cathedrals surrounded by buildings get a lens that will include eighty degrees on the base line.—4. Under some circumstances density is obtained by increasing the proportion of pyrogallol.

BONNE.—1. Stains may be taken out of engravings by the use of ozone bleach, as described by Mr. Brooks at page 244 of our volume for 1882. The strength recommended is one to ten, although it may be employed of double that strength.—2. Magnesium will be preferable to limelight.

PACO.—1 and 2. Give the plate a substratum composed of sixty grains of gelatine dissolved in ten ounces of water, to which three grains of chrome alum, previously dissolved in a little water, is added.—3. Clean the opals with pumice powder and water with friction.—4. Filter the emulsion through chamois skin.

H. C. M.—Two strands of magnesium will give double the light of one. Plain opal or porcelain will make an effective reflector. A common white dinner plate, or even a sheet of white cardboard, will answer the purpose equally well. The finest deposit can be obtained when using pyrogallol acid with wet collodion; but the finest deposit of all is that obtained with the albumen process.

R. C.—Both the orthographic and the triplet lenses may be considered obsolete, seeing that they are not now made. They are exceedingly good lenses, but have been superseded by those of more modern construction. They both gave exceedingly fine definition, but the former was not free from marginal distortion. The triplet is still used by many for copying, and it answers its purpose well.

VIOLETTE writes: "I have attempted to colour photographs after enamelling, and, as you see by enclosed specimen, I have been unsuccessful. Having prepared the glass, I put on the photograph, as in ordinary enamelling (Parisian style); I poured some olive oil on the back, which at once made the transparency; then I coloured it with oil colour, which will not dry; I mixed the colours with linseed oil and a little gold size; then I tried the crystalline mediums, but still find it will not dry. Will you kindly tell me how I could make the photograph transparent and at the same time make the colours dry?"—Instead of using olive oil, employ Canada balsam thinned with benzole.

SCHOOLMASTER puts the following queries: "1. What is the usual method of washing prints in order to free them from hypo? Will nine or ten half-hour changes followed by a night's soaking and a subsequent change ensure their permanence?—2. How can you determine whether a bromide print is fixed or not?—3. Will the quick printing paper, as advertised by several firms, give results similar to the ordinary sensitised paper? and is it permanent? Can sample sheets be obtained?"—In reply: 1. The usual plan is to submit the prints to running rather than a prolonged soaking in stagnant water. If the prints be treated with very frequent changes of water for two or three hours they may be more perfectly freed from the hypo than by a day's continuous soaking.—2. If the prints be kept moving about in a fixing bath of the usual strength for fifteen or twenty minutes, provided the solution be fresh, it will be sufficient.—3. Yes, if it be skilfully used. Sample sheets are supplied by most makers.

J. N. TULLOCH, M.B.—The nearer the aperture approximates to that of the human eye—or, to be still more accurate, to a mathematical point—the more correct will be the portrait. If you have access to the writings of Sir David Brewster, in or about 1861, you will find that he enters very fully into this subject; but mathematical accuracy has to give way to expediency, and a lens must have some dimensions, which in those days for large heads were very large. Such large lenses were his *lente noire*. But we refer you to what he said. Practically, the smaller the lens employed the better. You have knowledge enough of optics to understand readily that the stop or diaphragm forms really the effective aperture of the lens, and the accuracy of the projection is in the ratio of its diminution, and this, irrespective of whether the lens be a large compound one or a single one. The mere fact of a large lens, such as you describe, being able to see round a corner as it were, proves that it will not delineate a large head properly. If demonstration be required, stop the front wholly except a small aperture on, say, the right-hand side, and take a picture; repeat the experiment with an aperture on the opposite side of the lens, and on comparing the two pictures they will be found to be dissimilar, and cannot be superimposed to produce a perfect picture. They would require a stereoscope for their examination, when they will appear in stereoscopic relief. We here refer to a leading article on binocular cameras in the JOURNAL for January 21 of the current year, which applies to the case in point. To sum up, a compound lens to produce a large head similar to one attained with a single lens, must be worked under the same conditions as regards the stop.

PHOTOGRAPHIC CLUB.—The subject for discussion at the next meeting, March 30, will be *Lantern Matters*. This is a lantern night. Visitors are invited.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—On Thursday, the 31st instant, Mr. S. G. Buchanan Wollaston will give a demonstration on *Film Photography*.

MARBLE PORTRAIT OF MR. GLAISHER.—This portrait having been now completed, Mr. Toft, the sculptor, 12, Trafalgar Studios, Maures-road, King's-road, Chelsea, invites all photographers and their friends to call and see it and others on Sunday next between three and six o'clock.

MR. ALBERT P. BAKER informs us that his firm (the London and County Photographic Company), has obtained the exclusive right of photography of every description at the forthcoming Jubilee Exhibition in Manchester, and also at the Industrial Exhibition, Newcastle-on-Tyne.

MR. W. K. BURTON, C.E., being about to leave this country, it is intended to entertain him at dinner on Wednesday evening next, the 30th instant, at the Holborn Restaurant. The chair will be taken at seven o'clock precisely. The tickets will be 4s. 6d. each. All are invited. It is imperative that those intending to be present should signify the same before midday on Tuesday (the day previous) to either Mr. T. Bolas, 5, Farnival-street, Holborn, or to Mr. J. Traill Taylor, 2, York-street, Covent Garden, W.C.

* * ILLUSTRATED SUPPLEMENT.—With this number we give a portrait of Mr W. K. Burton. It is a very characteristic likeness of this gentleman, and is from a negative taken in a private room by Mr. Andrew Pringle.

THE BRITISH JOURNAL OF PHOTOGRAPHY.

No. 1404. VOL. XXXIV.—APRIL 1, 1887.

FLATTED OIL BACKGROUNDS.

It will be remembered that in the article on backgrounds a fortnight ago we mentioned that those prepared in what is termed flatted oil colour are amongst the best, both as regards durability and efficiency, a photographer, whether professional or amateur, could possess. At the request of several correspondents we here give such practical details as will enable any one to prepare his own, for it must be acknowledged by all that the photographer who is able to produce his own backgrounds is in a far better position than is he who is dependent upon the local decorator. Assuming that the work has to be commenced *de novo*, we shall begin with the fabric itself.

The most suitable material is that known as unbleached sheeting. It is strong, cheap, and it may be procured at the upholsterers in various widths up to about three yards, and of any desired length. The sheeting obtained, it must be strained on a stout wooden frame, or it may be nailed on to the wall, but the frame is by far the best. The next thing is to give it one or two coats of common size of the oilshops. The object of this is to render the fabric less absorbent, because if the paint were to be applied to the unprepared canvas it would be soaked up to such an extent that two or three times the quantity would be necessary to obtain a perfectly even coating. The size as purchased will require dilution with water before use, and it must be applied tolerably hot. About one part of size, according to its quality, to two or three parts of water is a good proportion. Two coats of thin size is preferable to one of thick. The canvas having been sized, it is now ready for the paint.

Paint of different colours, ready for use, is now sold by most oilmen. For backgrounds grey is generally preferred; this may be made by mixing some white and black paint together. It is always better to add the black to the white than to proceed in the reverse direction, as the effect of the mixture is then the better under control. A small quantity of black overpowers a large body of white, while the white has a far less influence on the black. It is a good plan to mix a small proportion of red—either Venetian or Indian—with the colour, as this gives the background a warm and less sombre appearance than it would have with the black and white alone. Oilmen will, if required, supply the paint ready mixed; but, on the whole, it is better for the operator to mix it for himself, because he can then make sure of obtaining the exact tint he desires, and this is not always the case when the colour is prepared to order.

The paint must be laid on, evenly, with a large brush—one that has been well worn by use is the best. A new brush

should be avoided, as it is liable to leave the work streaky. Two coats of the paint will be sufficient, provided the fabric was thoroughly sized in the first instance. If with two coats any unevenness is apparent, a third must be applied, as it is essential that the surface be uniform before the after operation of flattening is commenced. An even surface being obtained, the next operation is the flattening, by which the glossiness of the paint is to be destroyed. The usual plan adopted by painters and decorators is to mix some colour, of the same tint as the groundwork, with turpentine alone, and this, when applied to the surface, is immediately stippled over with a large badger-hair brush, two persons being engaged in the operation. In skilled hands this method answers admirably, but in the event of the tint, on drying, not proving the right one, it is necessary to paint the background afresh, as two coatings of this flattening cannot be applied in succession.

Here is a method of flattening, looked upon by many as a trade secret, which is well suited for the preparation of photographic backgrounds, inasmuch as several successive coatings, of different tints even, can be applied without repainting. This flattening is prepared as follows. White lead and lampblack, with or without the addition of red or other colour, are mixed together with turpentine, to the consistence of thin ordinary paint. So far this flattening mixture corresponds with the former one, except that it is made somewhat thicker, but the essential difference is that one-third by measure of japanners' gold size is afterwards added. The black and red colour may be obtained ground in oil like the white lead, but we prefer to use the colours dry, so as to avoid the introduction of oil which tends to produce glossiness. The mixture must be strained through coarse muslin before use. The advantage of this preparation over that previously described is that it does not dry so quickly, while the gold size, unless added to excess, gives no gloss. It may here be explained that if one portion of the work dries before the adjacent portions are laid on the junction is sure to show in the form of brush marks when the background is finished. Hence in flattening it is customary to work with the doors and windows closed, so as to avoid draughts, which would accelerate the evaporation of the turpentine.

The flattening preparation is laid on as evenly as possible with a large painting brush, such as that employed for the paint. It is then stippled over with a dry one. This stippling consists in gently dabbing the surface with the points only of the brush, so as to destroy the marks, if any, left in applying the colour, as the operator is scarcely likely to possess a costly badger-hair brush; a painter's ordinary "duster," or, indeed, any other brush may be used instead. On one occasion we remember using—and successfully, too—a common hearth brush for the

purpose. It is somewhat important that the brush used be composed of bristles, and not the fibre which is often substituted in the commoner kinds of brushes, because with these the fibres are prone to mat together with the colour and so produce patchiness. In stippling it is important that only the tips of the bristles touch the surface, and these should be kept as dry as possible by wiping or rubbing on a piece of old cloth.

With a little practice, owing to the comparative slowness with which this flattening mixture dries, one person may execute the whole of the work. But until this experience is acquired it is better for two to be engaged in the operation—one to lay on the colour and the other to do the stippling.

A PROPOSAL FOR A SENSITOMETER.

NEVER was the want more strongly felt than at the present time of a sensitometer giving greater accuracy of result and possessing a wider range of applicability than those in present use. Several important points in connection with orthochromatic photography seem to hinge mainly on the question of relative exposure, but there exists at the present time, so far as we are aware, no ready means of accurately making such a computation.

The Warnerke instrument, useful as it is for certain purposes, is entirely and hopelessly out of the question; for, independently of its readings being to some extent arbitrary and open to doubt, the results it gives with white and coloured light respectively are quite at variance with one another, owing to the character of the rays absorbed and given off by the luminous tablet. Spurge's sensitometer, or one on that principle, is, however, correct in principle and well adapted for the comparison of light, or screens, or colours of any description; but it is, unfortunately, not in general use, and is not easily constructed by an inexperienced hand.

We have ourselves experienced this difficulty in connection with the measurement of the comparative colour sensitiveness of different plates, and in the course of our attempts to overcome it a plan has suggested itself which, if not capable of yielding the accuracy derivable from Spurge's instrument, is much simpler and easier to construct, while it can be rendered sufficiently correct to be really useful. What we require is an instrument enabling us not only to compare the sensitiveness of two or more plates to light of one particular kind and to state the result in absolute terms, but also to compare the sensitiveness of the same or different plates to rays of different colours. Thus, we will suppose we wish to compare an ordinary with an orthochromatic plate in every possible manner: we have to test, 1st, their individual sensitiveness to ordinary light; 2nd, their individual sensitiveness to yellow (or other coloured) light; 3rd, the difference in their respective sensitiveness to ordinary and coloured light. In order to satisfy ourselves on these points, we should be in a position to make a statement something like the following, ordinary and orthochromatic plates being spoken of respectively as A and B:—1st, To ordinary light, A twice as sensitive as B; 2nd, using a colour screen, B twenty times as sensitive as A; 3rd, A one hundred times and B three times, say, more sensitive to ordinary light than to the light passed through a colour screen.

Until such *data* can be arrived at with tolerably strict accuracy, it is hopeless to expect to place orthochromatic photography on a truly scientific basis, or to remove the many doubts that now exist as to its value and its application. But

the means do not exist for the purpose, hence the suggestions we have to make, which are based upon actual experiments with a roughly constructed instrument such as we shall describe.

The principle we have utilised is that originally put forward by Mr. Alexander Cowan some years ago, when the question of sensitometers first arose, consisting of a sort of dark slide, fitted with a drop-shutter front carrying apertures of different sizes to represent different tints or degrees of rapidity. The claims in favour of this arrangement were that by arranging the dimensions of the apertures so that they bore a certain relation to one another, a plate, or plates, might be exposed to any kind of light—candle, gas, or daylight—and the duration of exposure necessary to produce an impression calculated in absolute terms, and thus plates of different kinds, or lights of different colours, compared with the greatest accuracy.

The objections raised to the proposal were, that in the rough model first exhibited to illustrate it, no allowance was made for the constantly accelerating speed of the drop, and that, consequently, the lengths of the apertures bearing a definite relation to one another, the direct comparison of their exposures was impossible. This fault is, of course, easily remediable, as it is a simple matter to calculate the dimensions of a series of apertures giving exposures strictly proportionate to each other, if (for there is an if) the element of friction could be entirely eliminated. Whether Mr. Cowan, or any other experimentalist, proceeded any further with this idea we are not aware, but such is the principle upon which we propose to work.

In constructing such an instrument the points we laid down were the following:—A total effective drop, that is, the longest exposure given of definite length to be divisible into tenths and hundredths. In order to avoid the trouble and inconvenience of calculating, measuring, and piercing a large number of separate apertures, a single three-sided aperture to be used, one side forming a curve representing the gradually accelerating speed of the drop. To overcome the resistance of friction as far as possible, the shutter to be of considerable weight; and, finally, in order to give the instrument as wide a range as possible, the aperture to be of fair dimensions.

These ideas were carried out in the form of an instrument which, though comparatively useless for the immediate purpose in view, as we shall point out, served to indicate where and in what manner the principle can be improved for practical use. A description of the instrument actually constructed will enable us to point to its errors and show how these can be modified.

In the first place, an ordinary printing frame was taken, and the front portion cut away in such a manner as to permit a "drop" of wood or metal to slide freely *almost* in contact with the glass or negative when in position, suitable guides being attached to retain the drop in place. With the construction of the "drop," to be presently described, the "structural alterations" were completed. In the inside of the frame, however, in the ordinary place of the negative a sheet of thin ebonite was fitted, having a slit cut along its centre in a direction at right angles to the fall of the shutter.

The most important part of the instrument had now to be considered—namely, the drop, with its various dimensions. The first point to be settled was the extreme limit of exposure, and this we decided, for the convenience of experiment, should be one-tenth of a second. It was clearly desirable that the shutter should get well into motion before the exposure com-

menced; a drop of two inches before the aperture opened was therefore allowed for. These *data* being fixed upon, we were able to calculate the dimensions and shape of the exposing aperture. The shutter was constructed of one-eighth-inch mahogany, with a heavy piece of inch-stuff at either end to give it weight, and had a sliding motion of a little over fifteen inches. This permitted the drop to be used in *either* direction, the exposure commencing in each case after a fall of two inches, of which more anon.

In cutting the aperture the following was the mode of proceeding: A base line was drawn across the shutter two inches from the slit in the ebonite screen, when the shutter was pushed to one end of the slide. The length of the base line is arbitrary, and may be made to suit any size of plate, but whatever its length it must be accurately divided into tenths. Upon one end of the base line a perpendicular is erected representing the length of drop required to give an exposure of one-tenth of a second on the maximum, the other end of the line being zero. If the speed of the drop were uniform, all that would be needful would be to connect these two points by means of a straight line forming a right-angled triangle, but this right line takes the form of a curve in order to provide for the gradual acceleration. The curve is formed thus: Divide the base line accurately into tenths and upon each division erect a perpendicular, the whole forming a series of ten parallel lines. Commencing next from zero, point off with the compasses the distance the shutter is computed to fall, in each one-hundredth of a second, from one to ten, joining these points to form the curve. The following are the figures for a curve representing a maximum exposure of one-tenth of a second under the condition given, namely, exposure to commence when the shutter has dropped two inches. The figures are in decimals of an inch, commencing with the perpendicular next beyond zero:—

·406	1·33	2·40	3·65	5·00
·850	1·85	3·00	4·33	5·80

Such an instrument will give a graduated tint starting from the point of longest exposure, and to read off the duration of the exposure it is only necessary to measure the length of the visible impression. Thus, in the instrument we have described, the length of the base line is $4\frac{1}{2}$ inches, that is, one hundred one twenty-fourths of an inch. With a strip of ebonite of that length divided into tenths, and one of the latter again subdivided into tenths, we are enabled to measure off the length of a "tint," each subdivision of one twenty-fourth of an inch representing an exposure of the one-thousandth part of a second.

We should, perhaps, modify the last statement by saying "*should* represent;" but, owing to the interference of friction and other causes, which we shall describe next week, in this case it is not so. However, as we shall show, there is nothing to prevent a tolerably accurate instrument being constructed on these lines.

THE BURTON Farewell Dinner held on Wednesday evening was a great success. Mr. W. H. Walker presided. About fifty gentlemen were present, some of whom came a distance of 400 miles to show their esteem for the guest of the evening. A very handsome chronograph, cased in oxidised steel and gold, together with a gold chain, was presented to Mr. Burton in the name of a few friends. We shall give a fuller report of the proceedings next week.

A QUESTION raised a week ago by Mr. Arthur Debenham, of Ryde, concerning the sitter's right to possess the negative, is practically

the same as if an author were to employ a printer to produce him a determined number of printed impressions from his manuscript, and were then to claim the types by which they were printed. The demand made is preposterous in the absence of a special arrangement to purchase the negative.

THE intimation concerning the forthcoming Photographic Convention given by Mr. Briginshaw in our Correspondence columns is one to which we direct the special attention of photographic societies, and more particularly of their secretaries. There are many matters, apart from the technical details of photography, which concern the whole body of the fraternity, that might be discussed with great advantage by delegates from the various societies, and an opportunity like this ought to be taken full advantage of.

PHOTOGRAPHY had quite a field-day at the last meeting of the Royal Microscopical Society. Many photographs of objects of particular interest, photographs showing the power of lenses made with the new optical glass, and others, again, illustrating the capabilities of orthochromatic plates, were exhibited.

So much has been said about the new glass, and Zeiss's objectives (with eye-pieces to correspond) made from it, all to the detriment of English manufacturers, that it will be satisfactory to put before our readers the *ex cathedra* opinion of one of the greatest living authorities, the Rev. Dr. Dallinger, President of the Royal Microscopical Society. They may be reminded that the new series of lenses consists of newly devised objectives, and special eye-pieces to be used with them. Dr. Dallinger, by means of constantly testing the power of certain of his own objectives, knew exactly what they were capable of performing in a certain direction. When he examined the new Zeiss objectives as against those of his own, he was not able to discern any real advantage that the former possessed when each was used with the new eye-pieces, though the Zeiss glass with its own eye-piece was in some points superior to the English glass with the ordinary eye-piece. Since that first trial English opticians have set to work upon the devising and constructing of new forms of objectives and eye-pieces with the Abbé glass, and the reverend gentleman's verdict upon them is as follows: "I am bound to say that the apochromatics from Jena did not impress me by this test (described) as having accuracy of technical execution equal to the object glasses (English) with which they were compared." At the same time, he was most hopefully and powerfully impressed with the potentiality of the system represented by the apochromatic lens he first examined. What the future may have in store for us in connection with lenses for photographic requirements specially cannot yet be stated, but that the new glass will be employed by English manufacturers, and employed to advantage, cannot be doubted.

It is a little surprising that the simple vacuum pumps made on the principle of the Gifford's injector, and so many different forms of which are used in chemical laboratories, are not more frequently employed for photographic purposes—exhausting air from drying chambers, increasing rapidity of filtration, and so on. Any amateur can make one for himself, all the power that is required being a small head of water, and the simple necessary apparatus only includes a little glass and indiarubber tubing worked in a manner needing very little experience. Our attention is drawn to this form of laboratory apparatus by the account given the other day in *La Nature* of a new arrangement of the kind made and sold by a Parisian manufacturer. The instrument previously made consisted of two tubes with coned ends, surrounded by a larger outer tube of greater diameter. The cones are directed to one another but do not quite touch; the outer tube is connected to the chamber it is required to exhaust. The apparatus is attached to a water supply tap, and the supply turned on; the liquid passes out of one coned aperture into the other, and then finds its exit at the end of this lower tube, and in so doing draws the air from the outer tube with it till a high degree of exhaustion is attained. In the new apparatus the cones are joined, and one, or two, apertures made at the line of junction which serve to withdraw the air from the exhausting pipe.

THE recommendation to use melted ice or snow when a sample of pure water is required is so girt about with the respect due to old age and authority that much trouble will be experienced before the possible fallacy of the method can be demonstrated. A very excellent example, however, of the way in which organic matter (its mainly objectionable accompaniment in delicate photographic experiments) may be retained by frozen water was not very long ago shown in the United States in the city of Syracuse, the City Board of which town actually forbade the sale of ice cut from Onondaga Lake for any purpose which would bring it into contact with food, so much organic matter being imprisoned in the ice as to have occasioned numerous attacks of a dangerous disease.

THE arrangements in connection with the forthcoming Manchester Jubilee Exhibition are gradually being matured, and the Secretary has written that "the photographic sub-section are devoting a portion of their space to a history of the rise and progress of the photographic art, and are anxious to hear of specimens or apparatus bearing upon this department of the subject. They will be obliged by possessors of any such objects communicating with them at the offices, Albert-chambers, Albert-square, Manchester."

DRYING PLATES BY WATER POWER.

NOTHING in the ordinary run of photographic operations has ever bothered me so much as the drying of plates coated with gelatine emulsion. I have spent much money in drying presses; have fitted up closets and rooms; have used packing boxes, patent boxes, desiccating chemicals, Bunsen burners, egg boilers, bad language, and even roasting-jacks, in my attempts to dry plates evenly and at a suitable speed, but never until I tried water power have I got anywhere near the object I aimed at. My experiments and efforts have covered a space of several years; the subject has never been entirely absent from my mind, yet it was only lately that I achieved the object I have so long aspired to. I have examined the drying arrangements of many amateurs and professionals; have repeated them on a smaller scale at home; I have consulted many authorities, read many books and letters. I have been recommended to put my plates in alcohol, to swirl them through the air, and even to freeze them. All these (bar the freezing) I have tried, but never yet got what I wanted in perfection. But I feel that I have not lived and laboured in vain, for now I can dry plates as I think plates ought to be dried.

I believe that there is much misapprehension abroad as to how plates ought to be dried in order to secure to them the highest qualities. Most people in this country seek to gain the point by a current of air. So far, well. But, as a rule, this current is set up by heating the lower strata of air, and so causing an upward current of *hot* air. I do not think that heat in any shape is good for gelatine emulsion during the drying process, and heated air carries more moisture than cold air, so that heated air would not appear even to be thoroughly conducive to drying.

Another method that has come under my notice seems to be practicable only on a small scale; at least, I have not heard of it in any larger establishment. It consists of inducing a current *above* the plates by heating the air of the higher strata in a flue or some such arrangement. I doubt whether the current among the plates is so great with this arrangement, but, at all events, whatever air is set in motion is cool air, and therefore I am inclined to prefer this latter arrangement where it is found practicable. But though I have tried both these systems in various forms, in boxes small and cupboard large, I never yet could depend on my plates drying in any particular time, and sometimes my plates never dried at all.

Among other frolics, I one time made a great cupboard, fitted it with racks, carried a three-inch pipe right up through the roof of the house, and there fitted on a "swagger" cowl; at the lower part of the press I fitted "wormed" pipes, through which I sent a current of strongly heated air, which permeated the pipes, and then came out again "into the empty vast and wandering air." In spite of all this, and in spite of Shakespeare, I never knew how long my plates would take to dry in the finest weather; in damp weather I knew very well that they would never dry at all. This is merely a specimen of the trouble I took and the money I spent. I tried many other plans. Of course, some of my arrangements dried plates, but they did not do so as I wanted, that is to say, evenly, without heat, and in a given time.

It is pretty well understood that there is a right way and a wrong way of drying gelatine emulsion. The plates may be dried too quickly; in some countries to my knowledge plate makers require to protect the drying operations by sprinkling the floors with water. In America, in certain seasons, this is quite common. At Craigleugh it is very uncommon indeed. I have known plates remain damp in the cupboard I have described for weeks! Plates may take too long to dry, and a plate that has taken over, say, twenty-four hours to dry is pretty sure to be unevenly dried, and quite certain to be of very little use for anything. Such is my experience, and I have never known an exception to this rule. As I never dried a plate under about eight hours I cannot say what defects very rapid drying produces, but those who know tell me that six hours is the minimum time that ought to be allowed, and I can say from my own observation that eighteen or twenty hours is about the longest time allowable if the plates are to be thoroughly good. On the whole, I imagine that from eight to twelve hours may be put down as a suitable time for the operation. I should think it very probable that so long as the atmosphere around the plates be kept quite cool the plates would take no harm, however quickly they might be dried, but this, on my part, is mere surmise, a style of argument I deal in as little as possible.

My last and my successful experiment consisted in the production of a strong and steady current of cold air. The air is quite cold enough at present for my purpose, but were the weather very warm I would certainly, and I could easily, cool it. I will show my first attempt in this direction, because it contains the germ of a good idea, though I found it too small in scale to fulfil all I require. There are two pumps known as the "Bunsen" and the "Fischer." Both produce currents by what I may call "suction." The Bunsen requires a long fall for the water supply down from the pump; the Fischer requires a long fall to the pump, or (what amounts to the same) a considerable pressure of water at the pump, as from a main by gravitation. I figure the Fischer pump to show the principle on which it works, but the one I had was far too small to produce such a current as I required for a good sized box. At A is affixed a tube leading to the ordinary tap, which is turned on till the water rushes out with some force at B. C leads to a pressure gauge showing the column of liquid supported; this I simply closed up, as I

did not require any such information. A strong suction is produced at D, in the direction of the arrow, of course. It is evident that if a tube be carried from D to the top or bottom of a box open at top and bottom a current more or less strong will be produced through the box. But the pump I have is only a small affair, and I found the current produced quite inferior to what I required. Still the result, when I used a very small box and very few plates, was so satisfactory that I determined to go into a larger line of the dry-plating business.

I thought that something in the shape of a fan might help me, especially as previously my most successful feats of drying had been accomplished in a large room, the plates being caused to rotate on a rack by a common clockwork roasting-jack. (This was fairly successful, and I was fairly happy until I got fairly roasted myself for "annexing" the jack from the culinary department. But I assure my readers I did *not* mean to steal it!) My water supply here is practically unlimited, so I resolved to use some of it to drive my little fan. There is in Langhelm a congenial spirit of the plumbing persuasion, and we put our heads together (one very thickly coated and curly, the other slightly different) and made a water wheel and a blower. Here is a drawing of the outside of it, it explains itself

A BC is a box of tin containing an overshot wheel of eight or nine "scoops," not buckets. The water comes in from the main D in a very thin jet (through the nipple of an oil tin) but with considerable force, and strikes the scoops at a suitable angle, so that the driving wheel revolves seventy to eighty times per minute, according to force put on the water. EF is the driving wheel, and is simply a bicycle

wheel sixteen inches in diameter. G is the wheel that drives the fan inside the box, and the part where the belt goes round may be adjusted at two inches or one and a half inch diameter at will. (I forget the technical name for this extremity of the axle.) Thus it will be seen the fan revolves at a considerable rate. The belt, a cotton one, is made very slack, just tight enough to cause the fan to rotate. A screw at X pinches the wheel and the fan to a baseboard at the desired distance. W is the waste pipe by which the water goes into a cistern below. H is a rubber tube two and a half inches internal diameter, and goes into the bottom of the drying box, which is an "England" pattern, but has its top bored with three-eighth-inch holes with bent tubes stuck in, to let out air but keep out light. The plates are racked in the box in a common drying rack, and the air blows up among them. I have dried plates right over the air hole in about five hours, and twelve hours suffice to dry as many as I can get into the box two inches apart.

The wheel and fan cost me about £2, but I suspect they would cost a good deal more if ordered in a casual way. The plumber and I picked up parts, such as the bicycle wheel, just as they came in our way, and he charged me only "cost price" for his time. I feel pretty certain that a current of cold air is the best means for drying plates, and some reader may have the same difficulty as I once had and the same water supply as I now have. At one time I dreaded plate coating, I don't object to it at all now.

ANDREW PRINGLE.

EXHIBITING AND EXHIBITIONS.

[A Communication to the Photographic Society of Great Britain.]

I THINK all will agree with me that the chief event of the year to our Society is the Exhibition, and that it is the duty of every member to make it as perfect as possible, so that those who are interested and want to know what is new in the science, and true in the art of photography, may come here every October and judge for themselves. The outside public learns from our exhibitions the progress one of the three wonders of the nineteenth century is making; and the photographer, whether professional or amateur, acquires a knowledge of what his brethren are doing, and perhaps picks up new ideas, fresher inspiration, and intensified enthusiasm.

The time is now coming when wise photographers who look ahead should begin to think of what they shall do for the autumn shows, although I fear that too many are content to send a selection from the work done during the summer—work done without any special reference to exhibitions. In selecting your pictures, it is perhaps needless to tell you to send of your best, but it is not given to every man to know what is his best. The good and the bad, like the often-quoted sublime and ridiculous, are sometimes so nearly related that it is difficult to class them separately. It is our occupation to pursue shadows, and photographers, especially when judging their own works, seem inclined to "listen with credulity to the whispers of fancy, and pursue with eagerness the phantoms of hope." The quality of a large part of the work now contributed is much higher than it

was ten or even five years ago; so that anything sent to future exhibitions must be something more than good ordinary photography, if it is expected to claim more than a passing glance from the visitors.

It is a great mistake to send too many pictures—it is giving points against yourself. By doing so you run serious risk of breaking the eleventh commandment, and being found out. I have often seen and admired two or three good pictures, but that admiration has dwindled down to something like disgust when I have come to a lot of inferior work by the same hand, plainly suggesting that the good pictures were flukes, or happy accidents, and that the photographer could not distinguish good work from bad. It is quite astonishing to me how so much bad work, even now, finds its way to exhibitions. Photographers who would soon see the mote in the eye of another man's photograph cannot see that there is anything the matter with their own. It is human nature, I suppose, to fancy that our own geese are swans, and it naturally follows that

"Like Katerfelto, with his hair on end
At his own wonders,"

we feel sure the public will be delighted with our apprentice efforts, which to us look so like the work of a master.

There were many things sent to the last exhibition—I saw them amongst the rejected, and, I may add, also on the walls—which showed a very imperfect knowledge of what ought to be offered for exhibition. Yet I must confess that curious inconsistencies sometimes occur. The stone that the mason has refused has been known to become the corner-stone of the building. I once saw a picture placed very high over a door, evidently taken at random from among the rejected to fill a space, which afterwards took a medal at another exhibition. I have also seen the reverse of this. I have known a picture which took medals in several of the most important competitions entirely rejected by the judges at a village exhibition.

It is very difficult to put any limit to the number of pictures to be sent by each exhibitor. I don't mean in the interests of the exhibition so much as of the exhibitor himself. It is possible to get weary even of great excellence. I take an illustration from the last exhibition. There were five large frames sent to show what could be done by a particular maker's camera, and which, therefore, should have been placed among the processes. Each frame contained a large number of small pictures, many of them quite exquisite little gems, all of them good, but so numerous that the eye tired. I was one of the judges, and, therefore, sworn by our inexorable President to study every picture, and I did not feel kindly to the hangers for admitting so many of these advertisements, beautiful though they were, yet the hangers had not hung all of the frames of the same kind sent in by this one exhibitor.

On the frames the exhibition depends for its general effect only second to the pictures they enclose. The harmonious effect of our last exhibition was seriously marred by the inappropriateness of many of the frames, and more especially by those of two conspicuous exhibitors, to which I do not think there would be any impropriety in alluding. There were some foreign pictures, so fine in themselves that they well deserved the place of honour they got, but they were shown in mounts so glaring and vulgar that they seemed almost to defy the hangers to accept them. Opposite to these foreign productions—also honourably placed in a centre, which the pictures well deserved—were some magnificent Yachting Scenes, in a frame that made an eyesore to that side of the room. These prints were mounted in cushion-shaped rims, set in red flock paper—a most disastrous combination. Metal rims always look cheap and common, and are only fit for the sixpenny positives done by our nomadic brethren on the beach; the cushion is the most inartistic of all forms; and nothing could be more damaging to the colour of a silver print than red flock; it is even one degree worse than aniline-dyed plush. Both sets of pictures reached the perfection of their kind, and it was vexing to see artists who could do such good work do themselves so much injustice by their way of showing it.

It is very difficult to give any definite directions about framing. Taste is so wide that it will not be dictated to; but there are some things so positively injurious to the general effect that they should be vetoed. The only thing at present objected to in the prospectus for the exhibition issued by the Council is the Oxford frame. To this might be added all oval frames, black frames, white frames (we had some white frames in the last exhibition), and all glaring and violent coloured mounts; the flocks are especially detestable, and there are some cold, blue-grey mounts, much affected by some exhibitors, which are utterly destructive of harmony. I should be sorry to object to novelty in framing, but I would strongly object to dangerous eccentricity.

It is easy to object, not so easy to suggest; but I will try. In an ideally perfect exhibition all the pictures would be framed in gold, or something that would look sufficiently like it. This is the rule at the

Royal Academy, and at nearly all the principal Exhibitions of Paintings; no card mounts of any kind are allowed inside frames, unless they are gilt. We cannot be so strict here; but we may ask our exhibitors to strive for something like conformity. English gilt frames are no doubt the best when cost is no object; but for purposes of exhibition, I am willing to admit that the German moulding, which has so much improved of late years, is good enough. I would also admit to Photographic Exhibitions light oak or other wood frames, or these frames partially gilt, so as to harmonise with the gilt frames; but I would abolish anything that would make a blot on the walls. I should also like to see the mats, or mounts, inside the frames gilt, or of some delicate warm tint. Crude white does mischief; so does cold grey. There is no necessity for these mounts to be so wide as they sometimes are made. It is not fair to take up the space in an exhibition where space is limited by a display of plain paper.

The above remarks on framing are said on behalf of the exhibition; it will be only just to say a word to the exhibitors on their own behalf. It is useless to deny that considerable damage was done to frames last year which ought not to have been done, and it is hoped that the cause has, to some extent, been discovered, and that it will not occur again; but exhibitors must not expect to have their frames back from an exhibition in all their pristine freshness. A good deal of damage is done at every exhibition, from the Royal Academy downwards. It has been calculated, I do not know with what truth, that the frames that go into the Academy each year come out again with about 2000*l.* of their value taken off them. A few years ago I sent an oil painting in a new frame to a Provincial Exhibition of Paintings. It was returned to me before the opening of the exhibition, because they had so damaged the frame and scratched the picture that it was not fit to exhibit. My advice, therefore, is,—Don't go to too much expense in framing your pictures, but let them be framed decently, and so that they will agree with others.

The back of your frames should demand as much attention as the front. You should be very careful that no nails project. When they arrive it is impossible to avoid stacking the frames together, and if nails project it is as much their nature to scratch as it is that of an angry cat, and damage must happen.

Never send two pictures of the same subject, unless the second picture illustrates a process, and is intended to be hung in the process corner. Nobody wants to see two pictures which differ only in size. However much you may appreciate your pictures you need not send a lot of them. I mention this because I have seen as many as three prints of the same subject hanging in this room at the same time, and in this particular instance they did not vary even in size.

And now I am going to say a few words on that very tender subject—hanging.

The first duty of those who provide an exhibition to which the public are admitted is that it should be sufficiently worth seeing to repay the latter for the trouble and expense of going to see it. To do this, what is worth seeing must be hung in the place where it can be best seen, and the whole show must have a good general effect. The second thought—not the first—must be for the exhibitors, and how to do them justice, if possible, and to do as little injustice as can be helped. That there must be some mistakes is inevitable, and always will be until this becomes a perfect world, when perhaps photography itself will be superseded by something better. Not only must flagrant injustice be avoided, but too strict justice also. A producer of a muddy, out-of-focus, slate-coloured enlargement, could scarcely but feel, when he sees his picture on the line, that he has not only been well hung—but gibbeted.

The difficulties in arranging the pictures increase year by year as new processes are added to our stock. There was a time when the only considerations that arose were, which were the best pictures, and how were they to be fitted together. No regard had to be paid to their colour, as they were all printed alike. Hangers now have to be always on the look-out that prints of different kinds do not get so near together as to murder each other. I have seen a vulgar, large, black-and-white head, printed on pink albumenised paper, utterly destroy a group of most delicately beautiful platinotype prints; and what could be worse to the general effect of a room, as well as to their immediate surroundings, than the cold, faded, slaty grey of bromide prints, especially when of large size? It is getting increasingly difficult to know what to do with such pictures, short of rejecting them altogether, or spoiling the exhibition. It is possible that in time these prints may be improved in colour, then these remarks will not apply.

I think that hangers and judges insist, sometimes, too much on anonymity, and perhaps I may add impartiality, although it requires all my temerity to say this. To begin with, it is impossible to keep up more than the pretence of the anonymous. An expert does not fail to recognise the work of well-known exhibitors, and it is scarcely fair that the

others should not be known also. It is absolutely necessary, if our exhibitions are to be representative, that the names of the exhibitors should be known to the hangers. There can be little doubt that an exhibition depends, apart from its business management, on its general effect and the beauty of the pictures exhibited, but there should be room found for a few pictures which have nothing pictorial nor any novelty of invention to recommend them, and their interest should depend solely on the name of the producer. I will give an instance.

When any man writes or talks a good deal which appears to be very sensible about photography; when he apparently spends a good part of his life in trying every plate and developer that is recommended, with a series of his own modifications to each of them; when he tests everything that he uses even to destruction, and is wildly anxious that his work should be permanent and never die—then it is interesting to see that man's work, that we may be witness to what use he puts his knowledge. In such a case, which is quite supposititious, it is not the beauty of the work which should be considered, but the interest is founded on what sort of work that man produces. An absolutely impartial and just hanger would perhaps turn these interesting works out. But an impartial man is a mere machine.

Here is another case for partiality which I commend. The works of members, always providing they are good enough and not excessive in number, should be preferred to the exhibits of those who only occasionally make use of the Society's exhibition at the cost of a few shillings. Of course, there must be exceptions to this rule, as to all rules. It may happen that an outsider sends in a supremely fine work—then all ideas of rights of the members should be thrown to the winds, and the fine work should have the best place.

Yet another instance of commendable partiality. If an old exhibitor (one who has done much for photography and photographers) sent in presentable work, I confess that I should not only consider the work before me, but I should certainly think of the benefits that man had conferred on the art; and if it could be done without injustice to others I should "be to his faults a little blind," and give his work a rather better place than perhaps it intrinsically deserved. This is another reason for knowing who's who.

Every year there are some complaints about the hanging, and it would be astonishing if in a society of nearly five hundred members a few grumblers could not be found; and sometimes, if we could only forget that no hangers are perfect, they have just cause. But the members have it in their own hands. I have not the authority of the Council for saying so, but I have no doubt that that body would welcome any member of the Society, who has any aptitude for the office, who would volunteer his help in the selection and hanging—and in sharing the blame. I mention blame only because there is never any real praise for hangers, however well they may do their work.

I hear it has been suggested that a real cure for all difficulties would be found in a committee of twenty-five to manage the selection and hanging. This appears to me to be a youthful suggestion, born of inexperience. Two Kings of Brentford might be well enough, but I cannot imagine twenty-five of them smelling at the same rose. It would be as easy to ask for five-and-twenty volunteers as to call spirits from the vasty deep, and as effective. It should be quite understood that the duties of those who undertake to arrange the exhibition do not consist in walking in and out of the room two or three times a-day, and finding fault, and interfering with the real workers. Five minutes of inexperienced advice is scarcely of any real assistance to those who have done the work for years. What is wanted in a hanger is one who can afford to give six or eight hours a-day for several days, and at the end to lengthen his days by stealing a few hours from the night.

To conclude, I should wish to impress on you three things:—To produce every year a few pictures especially for exhibition. To send only a few of your choicest works. To frame them reasonably, so that they may do no mischief to their neighbours or themselves.

Finally, when you find you have not got the best place on the walls, attribute the misfortune to fate, your luck, even want of quality in the pictures—anything rather than to the want of consideration or neglect of those hard-working and much-abused members, the hangers; and if you should find yourself rejected altogether, comfort yourself by thinking that it was all for the best.

H. P. ROBINSON.

CAMERAS, ANCIENT AND MODERN.

[A Communication to the North London Photographic Society.]

In commencing this paper, a reference to the simple camera obscura, invented by Baptiste Porta in 1650, may seem of little interest, but it demands some attention inasmuch as its pictures were admired and

wondered at for nearly 200 years before any successful attempt was made to fix them. History, certainly in the case of cameras, repeats itself, for when the camera obscura was employed for sketching, the inversion of the image was found to be inconvenient, and a plane mirror was fixed at an angle of 45° to rectify this. This arrangement has been over and over again invented for the use of photographers, perhaps on an average once a year.

Amongst photographic cameras the simple box form is the first to claim our notice, and it is certainly worthy of more attention, especially from those who make or adapt their own apparatus, than is usually accorded to it. For much outdoor work it is all that can be desired; it is perfectly rigid, requires no putting together, and for small sizes is quite as portable as any of the more pretentious modern articles. The camera itself being a plain strong box, answers admirably as a packing case to hold the entire kit, lens, dark slides, and cloth, it can be readily turned on its side for vertical pictures, and I can say from experience, that for seaside work in windy weather it is the handiest of instruments. A slight departure from its primitive simplicity in the shape of a rising front makes it almost perfect. Now for its defects. It can only be used with one lens, and this must have either a rack and pinion or sliding adjustment, and it does not look so scientific as a complicated patent double-acting, reversing frame, swing-back camera, so that people who don't know anything about photography won't think so much of you when you take it out. Still the fact remains that a simple cardboard box covered with leather and fitted with a nine-inch portable symmetrical lens, is in daily use for outdoor work by one of our most ingenious professional photographers, one who has, moreover, invented more than one camera possessing novel and useful points.

The photographic art was not, however, very old when its disciples found out that the plain box camera was not capable of such adjustments as would render it available for universal use. In the first place, only one or at most two lenses of different focal length could be used, and a means of greater range of focus was required for portraits at various distances, not to speak of copying and enlarging. An inner sliding body was therefore introduced, enabling the body to be extended to about one and three-quarter times its original length, and this form has survived to the present day.

This type of camera, though convenient enough for indoor use, soon proved too clumsy and heavy for the landscape artist, and between the years 1850 to 1858, quite a host of portable and folding cameras appeared on the scene.

As most of these are now quite obsolete, I will leave the inquirer after them to seek them at the shops of second-hand dealers and pawnbrokers, and speak of the only two which can be said to have survived till now. The simplest of all portable cameras is one having a flexible bag for a body with suitable frames at back and front to carry the lens and dark slide. This possesses all the advantages of the simple box with the added one of lightness and portability. The well-known Scenograph, which has received the commendation of so distinguished a photographer as Captain Abney, may be taken as a good example of this class.

The other and more important type of portable camera is that now universally known as the bellows body. This at once attained the precedence over all other forms, and has held it up to the present. On and about it everything that photographic ingenuity could do has been done, with the result that such perfect adaptability and precision has been attained, that the modern camera can almost lay claim to be akin with the telescope and microscope, as a genuine scientific instrument, scientific in its construction as well as in its object.

Before proceeding to discuss the details of the modern camera, a glance at the many cameras produced during the long reign of wet collodion may prove of some interest. Then the double dark slide was a rarity, and numerous plans were devised for preparing and developing the plate in the field; for the dry plates of those days, though sometimes satisfactory, were seldom trusted by the operator, who wished to make sure of getting printable negatives. Mr. Scott Archer, the inventor of the collodion process, introduced the earliest of these, and he was speedily followed by a host of others. Some of these were fearful and wonderful in their design. One actually contained material for three dozen half-plates, including spirit lamp, varnish, and oven powder colours for tinting the finished pictures. A full-sized tripod made its appearance on turning a knob, and the whole apparatus could be "carried by a lady without attracting attention."

A practical apparatus of this nature was introduced by Dubroni, of Paris, and was for many years sold in London. It consisted of a water-tight chamber with the lens in front, and a suitable receptacle for the plate at the back. The plate was collodionised and placed in position, the lens closed, and the silver bath injected into the camera

itself, and allowed to flow over the plate. When a sufficient period had elapsed the bath was poured off and the plate exposed. An iron developer was next squirted into the camera, and was replaced by changes of clean water; when development was complete the plate was removed and fixed in a separate dish. The inventor did not recommend putting hypo in the camera.

The same idea was improved upon by Professor P. Smyth on his journey to the Pyramids. There he used a small metal camera with small ebonite baths with glass sides as dark slides. The plate was collodionised, placed in the bath, and exposed and developed when convenient in the ordinary way. These instruments, although useful for some scientific purposes, failed to find much favour with photographers in general, portable tents being mostly preferred, and we will now pass on to a class of cameras once common but now almost extinct, those designed for stereoscopic work. Opticians still advertise pairs of lenses, but how often is a pair seen in use. In the face of the admirable and suggestive paper which our President has written in this year's BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, it may seem superfluous, nay, almost presumptuous, to say anything of them; but when the subject of cameras is to be dealt with, binocular cameras must not be left out, and even the less generally known single stereo camera with which the name of Latimer Clark has been for so many years connected deserves a word. With this camera a baseboard at least double the width of the body or more is used, and the camera slid from end to end exposing half the plate at the time. This method possesses the great advantage of being capable of giving positives on glass or paper which do not require to be transposed, as in the case of the ordinary binocular stereo camera. The movable central partition used when an ordinary camera is employed for stereoscopic pictures can also be usefully employed in taking single pictures of smaller dimensions. Thus, it may be used for bisecting the plate horizontally as well as vertically, thus giving the power of making panoramic views, while with the stereo division in its normal position two dissimilar views may be taken on the same plate, while the addition of cardboard or tin shields enables an almost indefinite number of subjects to be taken on one plate. Of course it is understood that a revolving or horizontal sliding front is fitted to the camera.

The bellows bodied camera in its modern form comes next, and it will be best at once to decide what must be regarded as *desiderata* in what may be termed a general purpose camera. Firstly, and obviously, it must be perfectly light-tight, and some of the cheaper makes do not meet this condition. Secondly, it must be rigid. Thirdly, it must possess considerable power of moving the lens to any part of the front board. And, fourthly, it should possess a range of focus from half to two and a half times, the longest side of the plate intended to be used thus permitting the use of wide angle and long focus lenses.

Some one will now probably ask, Why is the swing back not reckoned as an essential to this? I can simply reply that one of our most experienced outdoor workers makes all his pictures, including many architectural subjects, without ever using a swing back, and no convergence of the lines can be detected. Nevertheless, most workers will find the swing back a very useful addition.

A short description of types of outdoor cameras now principally used may be of some service, and it will be convenient to divide them into classes.

The first we will call the ordinary bellows body camera, a pattern which has, until the last few years, been the favourite for landscape work. In this form of camera the length to which it can be extended is limited, by the fact that the baseboard is single and that it has to be folded up against the focussing screen, thus giving the height of the camera *plus* the depth of the rigid part of the body as the greatest range of focus attainable. Many excellent cameras of this type are now in use and can be rendered available for long focus lenses by the addition of an extension front. Every improvement has been added to this type of camera, but it is now being rapidly superseded by the more modern or long focus camera. The pattern most generally approved is identified with the name of Mr. George Hare, and many of the instruments subsequently issued bear a striking family likeness to it. In this camera a great length is obtained by making a second baseboard travel over the original one, by means of a rack and pinion, the back being hinged on to the fixed baseboard while the front can be clamped on to any part of the moving one. These bolts, or clamps, also provide an excellent side swing to the front, as the arrangement of the back does not allow it to be placed there. This form of camera has one slight defect; the back swings from the bottom edges not from the centre, the theoretically correct position. This necessitates refocussing after the view is arranged on the ground-glass, not a serious trouble, but one to be avoided if possible.

The beautiful cameras of Mr. McKellen, of Manchester, are built on much the same lines, but with several useful modifications. Amongst these may be named a revolving front with the lens placed eccentrically, so that half or quarter-plates may be taken with the help of metal shields, a circular tripod top revolving in the baseboard and a swing front, so that no matter in what position the camera is placed the axis of the lens can be placed opposite the top or bottom edge of the plate. This arrangement is also useful when using wide angle lenses.

Another form of long focus camera is that in which the baseboard instead of having its halves sliding over each other has them arranged as in the old form, one folding over the focussing screen and the other over the lens, a hole being cut for the lens to peep through. This arrangement is very useful for wide angle lenses as there is then no baseboard to cut off the foreground, a defect to which some of the long focus cameras are liable. Cameras of this type have been introduced by Mr. George Smith and Mr. B. J. Edwards.

Besides the foregoing typical cameras, and leaving out the universal or studio form, there have been many cameras introduced for special purposes, all of which it would be impossible to speak of now, but the detective camera demands a little attention. Here the object has been to make the apparatus look as unlike a camera as possible—a book, a brown paper parcel, or a small portmanteau being examples of outer covers. With most of these the ordinary dark slide is used, but in some the plates are supplied from a small changing box as in Marion's Academy camera, or automatically, as in Mr. J. A. Harrison's metallic camera, or the vest camera, which only requires the operator to wear a soup-plate like arrangement under his vest with a lens peering through his button hole.

So far, only the camera itself has been dealt with, but dark slides and changing boxes must now be glanced at. In the earliest camera these were entirely wanting; the camera itself had to be carried into the dark room, the sensitised plate or paper fixed in position, and the whole apparatus replaced on marks which had been made at the time of focussing. The inconvenience of this was soon felt, and we find that Daguerre employed a dark slide opening with hinged doors down the centre. Almost immediately this was superseded by the ordinary single dark slide, which has remained in use almost unaltered to the present time. A few modifications in the shape of draining troughs for wet plates, and various plate carriers capable of adjustment, being nearly all there is to chronicle, although a shutter somewhat on the principle of an iron shop blind ought not to be passed over. The double dark slide is of almost equal antiquity with the single one, and has survived from the calotype days with but little modification, the principal improvement being the introduction of shutters which could be entirely withdrawn from the slide, the aperture being closed by a spring flap lined with velvet. A cheaper form of double slide has a solid frame, and the plates have to be inserted from the front.

With changing boxes there has been far greater variety. In the earliest forms the plate was shifted into the camera itself, an arrangement only suitable for small cameras. The ordinary dark slide naturally came into use with the changing box, and the best type now in use does not differ very much from those made by Ottewill many years ago. The great defect of changing boxes is the liability there is of plates jamming in process of changing, and few of our modern dry plates are sufficiently true to size to entirely avoid the chance of this happening.

It is, perhaps, hardly allowable to class the roller slide or roll holder with changing boxes, although it certainly belongs to the family, and it will be hardly necessary to describe the modern types, as these have been so fully described and illustrated recently, but it may be well to give the history as far as we know it of this piece of apparatus. In the April number of the *Journal of the Photographic Society* for 1856, Mr. A. J. Mellhuish described a roller slide which he had just then invented. It consisted of a rather thick dark slide, carrying two spools or rollers, from one of which the sensitive paper was wound off to the other as required; a small yellow window in the back allowed the operator to see when a fresh length was in position; a plate of glass in front, and a board pressed against the back of the paper with springs, ensured flatness of the sensitive paper, and completed the arrangement. This idea seems to have been little noticed, probably owing to the fact that for many years paper negatives were quite out of fashion, and it was not till a considerable time afterwards that Mr. Warnerke introduced an improved roller slide, which he designed for use with paper temporarily coated with collodio-bromide emulsion. This slide possessed some very good points, amongst them the revolving shutter, and an ingenious measuring apparatus which denoted by ringing a tiny electric bell when a fresh

surface was in position. Mr. Warnerke's slide stood the test of practical work, and has now, I believe, been adapted to the new gelatine negative papers. Finally the Eastman-Walker slide has come prominently into notice, and seems to have quite fulfilled the promises of its inventors and the expectations of those who have purchased it. Since the introduction of this slide a host of others have appeared, but none seems to differ enough to be mentioned in this paper, which can deal only with types of apparatus.

EDGAR CLIFTON.

ALPHA PAPER.

[A Communication to the Camera Club.]

THE question has been asked, and by a photographer, too, "What in the world is Alpha paper? Is it a curl-paper or a young ladies' journal?" It is neither of these, nor must it be confused in any way with the ingenious clothes-wringer and other articles of commerce blessed with the same arrogant title. It might be explained to some that this title gives no clue to its composition. The name is intended to be understood as that of a photographic printing paper which claims to be registered A 1, or as easy to work as A B C.

It is a rapid printing paper for obtaining positives by artificial light, and is subjected to much the same treatment in development as the argentic bromide papers. But it appears to have important points of difference from these, and, as in working, it shows such remarkable resemblances in behaviour to some of the well-known characteristics of the ordinary albumenised silver prints, it is generally described as a chloro-bromide paper. Others may be able to throw some light on this point.

Its first introduction was in 1884, and in some quarters it was hailed as a boon and a blessing to photographers. In one of the photographic papers it is remarked, "The inauguration of this process may be regarded as being almost as great an era in the history of photography as the introduction of dry plates."

These expectations were not, however, realised, and no further mention of the new material is to be found in the same journal for some years. At that time difficulties in working must have presented themselves, or the popular fancy had not yet been educated to admire photographs in black and white or monochromatic prints in warm colours other than those with a glazed surface. As illustrating the poor favour which it met with at first, many amateurs are still found having in their possession the unused remains of small packets which they purchased in the early days. Latterly, through improvements in manufacture possibly, it has come to the fore again, and for some time there has been a growing revival of interest in it. This meeting of rival enthusiasts is one of the signs of the change. Whether Alpha paper merits the brilliant future anticipated for it in the journalistic allusion already quoted or not, there is a very general opinion held that, on account of colour obtainable, latitude in exposure, sensitiveness to artificial light, and marvellous cheapness, it deserves to be better known and more widely used than at present is the case.
